NOTES AND COMMENT

A WORD FOR EMPIRICISM AND THE PAST

THERE is a tendency towards nihilism in therapeutics. The present generation is not content to keep an open mind with respect to methods which are not based on strict scientific evidence. Even a healthy skepticism will not satisfy it. It calls for the abandonment of all empiricism, and the professional excommunication of those who use its methods.

Yet, when we compare the therapeutic methods that we owe to empiricism with those with which experimental pharmacology has endowed us, the latter group is pitifully small in proportion with the amount of enthusiasm it arouses. Think of what we owe to empiricism: our only undoubted natural specific, quinin; iron in chlorosis; mercury in syphilis,—to name only three of our most valuable drugs.

This is not said in disparagement of experimental pharmacology, or of its distinguished exponents. The latter are not to be found among the fanatical decriers of empiricism. Experimental pharmacology has already done good work; it is called upon to play, in the future, the leading rôle in drug therapy. But it has not yet learned what are the least misleading means of research; the field that it has explored is small and the results provisional.

The discovery of the cause of malaria dates back less than forty years,—a long time ago, almost medieval, to the recent graduate, but only a short time in the history of medicine. Had the rigid methods of experimental pharmacology been applied to the use of quinin before Laveran's discovery, we make bold to say that our nihilistic friends would have classed its supposed specificity as an old wife's tale. Quinin is of doubtful utility as a febrifuge; its febrifuge action is not specific. Malaria is characteristically intermittent; it has capricious remissions and relapses, with or without treatment. The laboratory evidence pertaining to it would have been negative; the clinical, unconvincing.

Experimental pharmacology has now confirmed the empiricism of the Peruvian Indians. It would have been hard put to it to do so before the time of Laveran.

In Curzon's fascinating "Monasteries of the Levant," which gives a vivid account of the near East in the early thirties of the nineteenth century, there is a passage in which he pours scorn on the precautions taken by persons in Egypt to avoid infection, moved by the absurd idea of contagion. Much more recently a great explorer, still living, qualified as a ridiculous superstition the belief of certain African natives that fever was brought by the bite of certain gnats.

It has been characteristic of all peoples to estimate at the highest value the achievements of their time. We are all tempted to believe that we are living, if not at the apex, at any rate very near that point in the accumulation of human knowledge. We are told that about 1830 a Patent Office clerk resigned on the ground that there could not be many more inventions made. Though the superiority of the decimal over the duodecimal system of arithmetic was admitted, the latter was maintained at the time of the French Revolution because it was believed that the existing treatises and tables filled all the mathematical needs of the human race.

A recognition of the probability that future

generations will look on us as living in an unlightened age should make us more modest in our attitude toward the past. There are often new truths to be dug out of old wives' tales.

HEALTH CENTERS: A FIELD FOR RED CROSS ACTIVITY

TO the average layman the American Red Cross formerly appeared to be wholly concerned with emergencies. He was more familiar with its beneficent work in great catastrophes than with any other of its activities. Now, however, when he thinks of the Red Cross, there is brought to his mind not only these dramatic interventions, but also the steady striving for child welfare and intensive anti-tuberculosis campaigns.

The American Red Cross has put in the forefront of its peace time program activities in the field of public health. Definite proposals in execution of this laudable policy are contained in a twenty page pamphlet entitled "Health Centers: Field for Red Cross Activity."

What is a health center? A health center is defined as "the physical headquarters for the public health work of a community." In it, under one roof, all activities, public and private, for the amelioration of the public health would find a common meeting ground. It would, therefore, be the coordinating center of community health work. But it is clear that the Red Cross means much more than this by "Health Center," for in the pamphlet the following activities, among others, are laid down as normal functions of such centers: tuberculosis clinics, prenatal clinics, venereal clinics, mental hygiene clinics, dental clinics, out-patient clinics for the local hospitals, medical society meetings, and laboratories,—all this in addition to the work having its headquarters at the center and its field elsewhere.

The conception is certainly ambitious, not, however, impossible of realization. As the pamphlet is read one seems to see the scope of the idea enlarge before him as the writer warms to his subject.

Cooperation of the closest kind between volunteer health activities and the public health authorities is regarded as one of the aims of and one of the natural consequences to the proper operation of a health center. It is clear that the author of the pamphlet looks upon the health center as one of the most important stimuli to efficient work of the public authorities, under whom, when they rise to the desired level of efficiency, all such work will eventually come. In this connection Doctor Farrand has said: "Without in the slightest degree grasping or usurping the field of any other organization we can get behind these bodies and insert a new kind of cement, a new kind of binding material, that will hold them together so that they will find that they are forming one great forward movement for the welfare of the country."

This is the second field of activity in the amelioration of public health conditions, the first being the admirable work of the Department of Nursing. The team work of the public health nurse, the health center, and the public authorities cannot fail to produce an immense improvement in health conditions throughout the country.

The appropriateness of the Red Cross as the source of inspiration and as the uniting factor for such work will scarcely be disputed. Its widely representative character, its impartial attitude towards all parties and groups in the community, and its world-wide reputation for achievement leave it without a competitor. Whether the health center, *i.e.*, the building housing it, be owned by the Red Cross or not, will be a matter to be decided for each case on its merits. But the use of Chapter funds for the construction, equipment, and operation of such centers, or for contributions thereto will be officially authorized as a legitimate Red Cross expenditure.

The Public Health Officer of the community, backed up if necessary by the district or headquarters representative of a state health department, should be expected and encouraged to take the lead in bringing together the various officers in planning and developing a health center. If for any reason this is not now practicable, the voluntary health agencies of the community may well take the initiative for the coordination of the health work in the manner suggested. Every legitimate group working in the interests of public health should be invited to participate.

Before beginning the work, a community survey is urged, and advice from the Division Office should be obtained. Certain familiar Red Cross activities which are already established can well be brought into the new health center. Such functions are the public health nursing, the classes in elementary hygiene, home nursing, dietetics, and first aid. Again, in the case of a local disaster the health center may prove of inestimable value in furnishing a relief headquarters already equipped in many essentials of supplies and personnel.

The relationship of the health center to the Junior Red Cross and to the public schools is also taken up in the pamphlet.

A special building is desirable but not essential, and the health center is especially urged as a

most fitting war memorial. Modern civic pride demands appropriate and dignified housing of libraries, courts, and schools. This attitude should now be extended to other governmental functions, especially to the work of the health department.

The health center serves as a clearing house for public health information and offers opportunity to coordinate all the public and private activities of the community. If the health center in a small community begins only as a bureau of information, it performs a useful task. The Red Cross can make no better beginning in its health work than by providing a headquarters known to the whole community as the place where information may be had promptly, as to the medical, nursing, and hospital facilities available in an emergency. How a local chapter may proceed in establishing a health center is described in the last few pages of the pamphlet.

In turning gradually from its war activities to peace and to thoughts of the work to be done at home, the American Red Cross has consecrated itself anew to its ancient and endless task of preventing and relieving distress and suffering.

A DEPARTMENT OF PUBLIC HEALTH NURSING

BEGINNING with the March issue, MODERN MEDICINE will carry a department of nursing which will be conducted in cooperation with the National Organization for Public Health Nursing, with Katherine M. Olmsted, secretary of the Middle Western office, as editor. We believe that through this department our readers will be enabled to tie up modern health cativities with the machinery of investigation and achievement, and that it will afford definite help in recognizing and in providing for their individual problems.

In Miss Olmsted a particularly happy choice has been made for the editor of this department. Graduated in 1912 from the Johns Hopkins Training School for Nurses, she was first associated with the staff of the Baltimore Instructive Visiting Nurse Association, for which Association she later made a special survey on causes of blindness, and the care of the blind. The social service in the wards of the Johns Hopkins Hospital which she instituted brought her in close contact with the charity and health agencies of Baltimore. She did pioneer work in Illinois in the development of rural nursing service.

For two years Miss Olmsted was connected with the Wisconsin Anti-Tuberculosis Association as state supervising nurse and director of the course in Public Health Nursing made possible by the close affiliation with the extension department of the University of Wisconsin. This position made it possible to study and assist greatly the actual development of Public Health Nursing in both rural and town work by means of personal contact and through the publication of frequent bulletins for nurses.

As a Red Cross Nurse Miss Olmsted was sent with one of the first units to the war zone with a special commission composed of experts in public health, sanitarians, and sociologists to make a study of health conditions in Roumania. While in war service Miss Olmsted started Public Health Nursing and conducted clinics and an outpatient department from a military hospital for the women and children along the eastern front under most horrible and uncertain conditions in the devastated, starving, typhus-stricken areas among the Russians, Roumanians, and Armenians. After her return to America, Miss Olmsted became a secretary of the National Organization for Public Health Nursing, and during the last year has started and directed a western office for the greater stimulation and extension of Public Health Nursing throughout the West and Middle West.

Three demonstrations of Public Health Nursing in three distinct types of rural counties have been started and directed by Miss Olmsted for the Federal Children's Bureau in an effort to promote better care of mothers and babies in rural sections and to discover if possible (1) what is the legitimate scope of activities of public health nurses in rural counties where services are maintained by public and private funds; and (2) how can funds be secured in the average rural county to finance an efficient, adequate public health nursing service. By experience and present activities she is particularly well fitted for the work she has undertaken with this magazine.

THE WORKING DAY

EULOGIES addressed to the Germans have not been a conspicuous feature of our newspapers of recent years; yet when, a few weeks ago, it was announced, with what authority we know not, that the German workmen had decided on a ten-hour working day, their decision was acclaimed with fulsome praise and their attitude contrasted with that of our own workmen to the disadvantage of the latter. Cartoons showed the industrious Teuton hard at work to increase production and to decrease the cost of living, while the American stood idly by.

The assumption that in a year made up of long working days the output would necessarily be greater than in one of short working days is

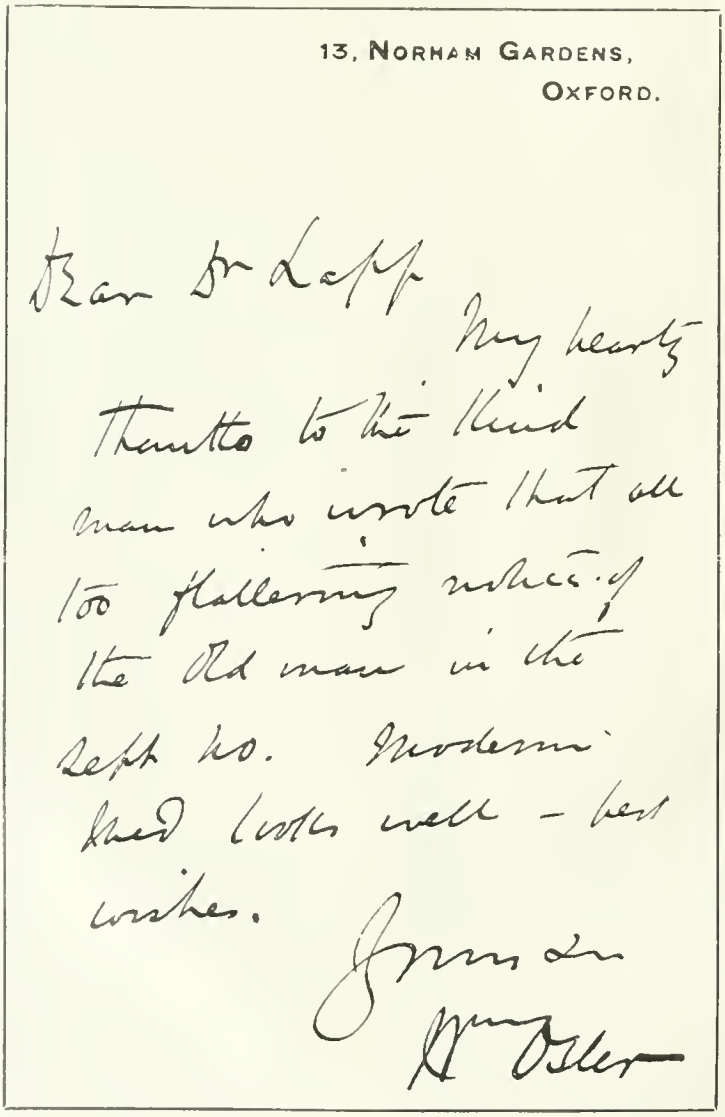
notoriously false. It is true that, for relatively short periods, especially under strong incentive, the longer day gives the larger output. But it is known that there is a reaction in this latter case and that, if an attempt is made to continue the "drive," the result will be a lowered output combined with a deterioration often amounting to a complete breakdown of the human machine. Nor is the incapacity necessarily temporary; it is sometimes permanent and usually obstinate. Of the ill effects on working capacity we have had only too serious an example in the person of the Chief Magistrate of the Republic.

Data have been collected, especially by the British Health of Munition Workers Committee, whose analysis leads to the conclusion that the upper limit of the efficient working day is, for most industries, not greater than eight hours, while for many it is certainly less. By efficient working day we mean the day which gives the maximum output while permitting complete recuperation during the hours of rest.

We cannot afford to treat our labor as we are said to treat our machines, —work it to full capacity until it is worn and then scrap it. We must conserve labors and to this end we must look to the output, not by the day, but by the lifetime. The arrival in this country of Lord Leverhulme, who is so well known as the advocate of the short day, has caused a movement of interest in the daily press. His position as one of the greatest employers of labor in the United Kingdom, as the founder of a manufacturing business which has become the largest of its kind in thirty years, lends a weight to his views which is regarded with apprehension by the long hour advocates. There is little room for sentiment in cost accounting, even for the sentiment of self-satisfaction in justifying one's attitude. It is therefore evident that employers would not attempt to enforce longer hours if they were convinced of the greater economy of shorter days. If the professional advisers of employers will bring to their notice the results of recent investigations on industrial fatigue,[1] the employers will meet the demand for shorter hours.

SIR WILLIAM OSLER DIES ABROAD

SIR WILLIAM OSLER, physician, scientist, and author, died December 29, after an illness of several weeks at his home in Nordham Gardens, Oxford, England, aged seventy years. He was born in Canada and received his medical degree from the McGill University, Toronto, in 1872. He was well known in the United States, having been professor of medicine at the University of Pennsylvania, and at the Johns Hopkins University, Baltimore, from 1884 to 1904. He resigned the latter position to become regius professor of medicine at Oxford, the highest honor in the bestowal of British institutions of learning. He was the author of many books of medical research and of philosophical studies, and his fame as a joker and as an epigrammatic and witty member of society was widespread. It was in 1905 that Dr. Osler in an address spoke of the "comparative uselessness of men above forty years of age," a remark which went round the world.



13, NORHAM GARDENS,
OXFORD.

Dear Dr Lapp

My hearty thanks to the kind man who wrote that all too flattering notice of the Old man in the Lesk Mo. Modern Med looks well — best wishes.

Yours ever
W Osler

Facsimile of letter written by Dr. Osler shortly before his death to the editor of MODERN MEDICINE, under date of November 3, 1919.

[1] A valuable bibliography of recent literature on industrial fatigue is published in *The Journal of Industrial Hygiene*, May, 1919, as Part III, Appendix VIII, of an article by R. A. Spaeth on "The Problem of Fatigue."

THE UNDERLYING CAUSES OF THE NARCOTIC HABIT

By ALEXANDER LAMBERT, M.D., New York*

TO understand the underlying causes of narcotic addiction one must go deeply into the personality of each individual. Social customs permitting the use of certain narcotics in moderation have covered over the real causes why these same narcotics are used to excess.

Most people think of drug addicts and drunkards as a class and mass of humanity, but, unless they are taken as individuals and their individual problems studied, the underlying causes of their excessive indulgences in narcotics will never be understood.

PERSONALITY AND DRUG ADDICTION

The control of narcotic drugs and the care of those addicted to their use are properly public health measures, and depend for their ultimate solution largely upon the case with which patent medicinal nostrums are available to habitués.

The underlying cause of drug addiction is to be sought for in the psychology of a personality unable or unwilling to face individual problems; difficulties, disappointments, or defeats call for an anodyne to bolster up the ego, or to afford escape from painful experience. Solve the personal problem, and the individual is freed from the need of narcotic forgetfulness.

The Use of a Social Stimulus

For centuries alcohol has been interwoven with our social customs to such an extent that it is difficult for us to think in terms of hospitality and leave out the use of alcohol. This fact as much as any other has tended to over-shadow and hide the real reasons for over-indulgence in alcohol.

In this contribution there is no intention to deliver a thesis on alcohol or alcoholic indulgence, but drug addiction cannot be understood unless it is coupled with the knowledge of alcoholic intoxication and the fact realized that the excessive use of both opium derivatives and alcohol is often for the same purposes, and frequently exerts the same effects on personality. In youth it is for the inflation of personality and the endeavor to feel and enjoy life more abundantly. In later years of life it is usually to forget things that one is unwilling to face or cannot face in consciousness, as if something must be found to benumb the mental suffering. From time immemorial all nations have sought something to help celebrate their joys, or something wherewith to cut the keen edge of sorrow.

Let us consider first what are the effects o these different drugs on the human organism. Alcohol first paralyzes the judgment and inflates personality; that is, as the judgment atrophies the self-conceit hypertrophies. Difficulties diminish or vanish; physical and mental enjoyment of life is greatly intensified. As the paralysis of mental function continues and increases there is approached the stage of perversion and stupid distortion of mentality and, finally, forgetfulness and obliteration of consciousness. All this is familiar in the early exhilaration by alcohol, and later the narcotic stupefaction. Cocain is not a narcotic, but is a pure exhilarator; it stimulates the mental and physical functions; it intensifies the accuracy of the senses and the mental enjoyment of them. It renders the senses not only more alert, but intensifies the rapidity of the physical response to action, so that men think and act more quickly. It distorts the judgment, blunts the sense of proportion, and destroys the ethical and moral sense. It produces a contented certainty of mind that all one dreams and hopes for will surely come to pass.

Cocain Destroys Ethical Sense

Among the early symptoms of its poisoning are ideas of persecution and suspicions in resentment against which the cocainist is quick to act. The cocainist is prone to carry weapons to defend himself against imaginary injuries or persecutors and is therefore a menace within his environment, especially as increased liability to act is coupled with distorted judgment and blunted sense of responsibility. The intensity of the action of cocain has its equal reaction in the intense nervousness and depression of its deprivation. The further excessive use does not produce sleep or a narcotic action as alcohol. There is no narcotic action in cocain.

Heroin is not an alkaloid found naturally in opium, but is built up synthetically from substances found therein Its effect is to inflate personality, giving the exaggerated sense of egotistical importance, soothing hurt feelings and disappointments, and benumbing judgment. It acts

*Read before the New Jersey Sanitary Association, Lakewood, N. J., December 5, 1919.

similarly in many ways to cocain; while its action is not so intense, neither is its reaction and depression so distressing. Its effects last longer than cocain, and the dose does not have to be so often renewed. It does not produce the mental de-

Miss Sara Graham Mulhall, deputy commissioner of the New York State Narcotic Commission, toward whom attention has been directed for the work she has done in arousing public sentiment against the drug evil. (Photo by Underwood & Underwood, N. Y.)

generation and distortion with delusions of persecutions as cocain, but it does relieve pain and bring on narcotic sleep and forgetfulness when taken in doses beyond the stimulating amounts.

The stimulating and pleasing effects of small doses of morphin, its ability to relieve physical pain or mental suffering, and the degenerating and narcotizing effect of its continuous use are too well known to need repetition here.

Addiction Easily Established

From whatever cause the habit of taking these drugs may originate, it is the continued use over a certain length of time of small doses which produces the habit or addiction. Given a group of persons in health, or sick with some disease, who take small doses of these drugs for three or four weeks continuously, and the majority will be unable to cease taking them should they desire to break off. The deprivation from their accustomed dose will produce such physical suffering and nervous distress that the great majority cannot go through it and cease using their drug. Probably a greater number of those who were using the drug because of disease will succeed in breaking away from it than of those who began using it for causes other than disease or pain.

Alcohol, cocain, and heroin are the drugs, therefore, which attract mankind in the years of his youth and excessive indulgence is based on the desire to feel and enjoy life and its sensations more intensely and more abundantly. They are taken because of their power to inflate personality. In the years of youth, narcotism and forgetfulness are not sought, but the relief of strain, the soothing of hurt feelings and disappointments, the relief from the bitterness of being misunderstood. They are used to sustain personality in crises which, without them, there is dread of failure. They are used by the inadequate personality to lean upon for strength and encouragement when situations arise with which, unaided, the inadequate personality cannot cope.

A Reaction to Failure

One of the most frequent reactions to **failure** and disappointment in personalities lacking courage and fighting vigor, is a growing sense of inferiority. This, in the past, has been a common cause for over-indulgence in alcohol, for, by artificial inflation and an increased sense of swollen ego, relief was obtained. Cocain and heroin supply the same relief, and many instances of addiction are due to this often unsuspected cause.

Bad associates and evil environment are probably today the chief causes producing heroin addiction among the youthful habitués. The large majority of those addicted to this drug are below twenty-five years of age and certainly under thirty. As many small boys take to tobacco smoking because it appeals to them as a manly or grown-up thing to do, so do many youths, under evil environment, take to alcohol or to heroin. Moreover, an addiction to heroin could be hidden, while alcoholic indulgence could not, and the over-indulgence in heroin would seem more like physical fatigue and be less suspected.

Alcohol has had, from time immemorial, certain customs connected with its use which not only sanctioned its use, but defended and forgave excessive indulgence. These same customs covered over the real reasons why many men turned from moderation to the excessive use of it. The narcotic drugs have no such customs connected with their use in our civilization and the addiction to their excessive use has always carried with it a moral stigma. The stigma of moral degeneration, often undeserved and unjustly placed on the unhappy victim of the habit, has only in recent years begun to be removed. The more charitable point of view has extended to the victim of morphin addiction

more than to users of other narcotic drugs, because morphin is so often taken to relieve physical suffering. Few realize that nearly 80 per cent of the morphin addicts have acquired the habit from legitimate medication, sometimes wrongly used, but often, it is true, correctly and rightly given to relieve suffering. These unfortunate takers of morphin should not be classed as addicts; they usually have fallen unconsciously into a habit from which they cannot escape. If they have an incurable disease with suffering from pain, they should be given their morphin in doses sufficient to relieve it; but the giving of the drug should be carefully supervised, as all morphinists are prone to take more than they need through fear lest they may suffer. These patients should be franked by the health authorities, that they may obtain their drug in any state, without being imposed and preyed upon by unscrupulous persons.

Desire Narcotic Forgetfulness

The motives in life change after youth has passed, and in the early thirties social customs or early weariness of life are the most common causes of alcoholic excess and the underlying causes of all narcotic addictions begin to be more those of a desire for narcotic forgetfulness and less those of a desire for inflation of personality. The use of narcotics after thirty is in the majority of cases based on the inability to break off a previously acquired habit, or is a habit acquired because of disease or suffering from some injury. The usual drug is therefore morphin, though heroin may be used to allay pain.

As the age of the narcotic addict increases, so do we find an increase in the number of those who use the drugs to ease the weariness of life; to forget sorrow, ruined hopes, and lost opportunities. Alcohol in excess after forty, is usually used for its narcotic effect of blotting out some remembrance. Morphin is the usual addiction, though often in the rural districts one finds laudanum and crude opium the predominating form of the drug.

Through the kindness of Dr. S. Dana Hubbard, of the New York Department of Health, we are enabled to present herewith the statistics of 2,723 narcotic addicts, applicants to the drug clinic of the New York Health Department.

These statistics bear out the deductions of our previous experience. As one would expect in such a clinic, the group contains mainly the youthful addict of short duration of habit who has drifted into the addiction as a vice through evil association, using the drug characteristic of that type, *i.e.*, heroin. Of the 2,723 addicts 2,216 were men and 507 women. Of these 80.5 per cent were under thirty years of age, nearly one-third of the entire number being between twenty and twenty-five years of age, and about the same number of the total being native born Americans. Sixty-five per cent of the addicts took heroin alone, and 14 per cent added cocain to the heroin; 18 per cent took morphin. Nineteen and five-tenths per cent were over thirty years of age, and only 12 per cent had been addicted to their habit for more than ten years.

The underlying causes of addiction, as given in their own statements, were bad associates in 71 per cent; illness or relief of pain 18 per cent, and

only one per cent gave the reason for taking the drug as sorrow or other forms of trouble. In the article about to be published from which these statistics are taken Doctor Hubbard draws some further conclusions from his study of the situation in New York to-day. It is evident that the number of narcotic addicts has been enormously exaggerated and instead, as claimed by some, of comprising 1 per cent or 2 per cent of the population, it is probably not more than one-quarter of 1 per cent. The Harrison Law strictly applied in New York has produced but about 6,000 addicts, instead of the 100,000 or 200,000 as was claimed and expected. The exemption permitted under the law claimed by physicians for persons ill who must take their drug or suffer unduly, has been only 250. It is very noticeable, also that the physical condition of these addicts is usually not that of a narcotic morphinist—that of the thin, pale, cadaverous type of individual rather mentally dull, but the majority have been the younger, alert type which is seen in the stimulated class rather than the narcotic class. All these observations, therefore, confirm the domination of heroin in the addict of today.

Women drug addicts wait in the rain for hours for the anodyne which bolsters up the ego, or affords escape from painful experiences. (Photo by Underwood & Underwood, N. Y.)

Doctor Hubbard says that very many of these unfortunates are easily and quickly determined as showing feeble-mindedness which in young girls tends so strongly to prostitution.

Use of Narcotics Not Increasing

The question is often asked whether or not the present prohibition of alcoholic beverages will increase the other narcotic addictions. It seems to me doubtful if it does to any appreciable extent. Much will depend on the ease with which various medicinal nostrums are available, containing various percentages of alcohol and of narcotic drugs. The success of the present prohibition will depend in much larger measure than is usually realized, on the freedom permitted the patent medicine vendors to sell their wares. Many of these nostrums contain alcohol in amounts sufficient to cause acute and chronic alcoholic poisoning when used as continuously as recommended by the manufacturers. One serious defect of the Harrison Law is that it permits the sale of mixtures containing less than two grains of opium to the ounce. This permits the unrestricted sale of paregoric and similar medicines. Public opinion will doubtless remedy these defects when their full effect for evil is appreciated and will soon place the legal control of the enforcement of the narcotic laws and the care of the addicts under the state or municipal health departments, where it rightly belongs. Other temporizing experiments will be tried, but in the end the control of narcotic drugs and care of those addicted to their use will be treated as public health measures.

The customs surrounding the use of alcoholic beverages have been so interwoven with our ideas of social intercourse, goodfellowship, and hospitality that the parallel ceases between alcohol and other narcotics as soon as you leave the pathologic side of their effects on the body and consider the social side of their use. The abuse of

More than 3,000 victims of the drug habit have registered at the municipal bureau in order to get the artificial aid necessary in order that they may face existence. (Photo by Underwood & Underwood, N. Y.)

alcohol has long been condemned, but its ordinary use sanctioned. The use, even, of narcotic drugs, has always been condemned, except as medical means to relieve suffering, and their abuse still carries with it a stigma never possessed by over-indulgence in other substances. As already said, not only are there no social customs to sustain their use, but their use tends to anti-social rather than social results since they are used to escape and forget the responsibilities and duties of life and are the means by which the necessity to face the realities of life may be avoided.

Personality Studies of Drug Users

Over-indulgence in alcohol produces tissue changes in the various organs of the body and, if continued, these changes become permanent and progress until they themselves constitute disease processes. On the other hand, the excessive use of the narcotic drugs of opium does not produce tissue changes in the various organs nor cause changes which constitute disease processes. They do pervert the functions of various organs but, when the poisons are removed, the functions of these organs can be restored. The problem of the underlying causes of narcotic addiction lies in the psychology and personality of the individual, and so does the solution of the problem. If you can solve the individual problem which leads to the addiction, you will solve the means by which the individual can be freed from his addiction. The feeble-minded and inferior personalities are a separate group which need institutional and special care; but the ordinary addict, relieved of his drug and physical suffering, and cared for until he can face his existence without artificial aid, can be relieved of his addiction; and if his problem is solved, he will not go back to his narcotic.

Not infrequently a habit is continued after the original cause has ceased to exist, and the habit must be continued because of the physical suffering which unaided deprivation brings. Many addicts loathe their habit, but physically cannot break from it. Most of them when free are anxious to remain so. Hubbard's experience with the addicts under the Health Department sustains this view. He writes that "our experience seems clearly to indicate that the individual addict has only to be taken off his drug, and made bodily comfortable, and away from his old associates, and he will redeem himself. Off the drug and life's path made comfortable by suitable guidance, the addict, like every normal individual, faces his daily problems and can do so; but to stand alone requires after-care until he can feel at home in his new surroundings. This may take several months, but with such help redemption is sure."

This is a more optimistic view than is held by many physicians; but even among the medical profession the underlying causes of narcotic addiction are not generally understood. The under-

The control of narcotic drugs is indicated by the long line waiting at this municipal bureau, where reduced doses are administered which gradually lessen the hold of the habit. A separate entrance is provided for the women. (Photo by Underwood & Underwood, N. Y.)

lying causes of narcotic addiction are more personal than social. It may be summed up by saying the causes lie in youth in the desire to live more intensely and to dream of his future greatness. After youth has passed, they lie in the desire to forget the weariness of living and to blot out the remembrance of lost opportunities. They begin and end in the realm of personality.

AMERICAN MEDICAL SCHOOL IN PARIS

The establishment of the American Medical School in Paris, France, has been definitely decided upon. It will be entirely postgraduate in character and will be under the joint direction of American and French physicians.

ENDOWS CHAIR OF SURGERY

A chair of surgery with an endowment of $100,000 is to be established at the medical school of the Western Reserve University, Cincinnati, Ohio. The endowment is the gift of Dr. George W. Crile, chief of the medical staff.

COLORADO HAS TRAVELING DISPENSARIES

Two traveling dispensaries will be operated during the coming year by the Colorado Public Health Association for the benefit of citizens who are too sick or too isolated to secure the services of a physician. Remote settlements where there are no doctors and nurses will be especially benefited.

SIX-YEAR COURSE FOR CANADIAN

The medical course in the Western University, London, Ont., will be, with the opening of the 1919-20 session, six years except that those who matriculated and then left for overseas service will be on the five-year plan. The new plan is the same as that in force at Queen's and Toronto Universities.

OCCUPATIONAL THERAPY AND VOCATIONAL GUIDANCE FOR THE TUBERCULOUS

By H. A. PATTISON, Medical Field Secretary, National Tuberculosis Association, New York City*

THAT uncompromising apostle of Truth, John Ruskin, has said in an address on "War"[1], "It is an assured truth that whenever the faculties of men are at their fullness, they must express them by art; and to say that a state is without such expression is to say that it is sunk from its proper level of manly nature. So when I tell you that war is the foundation of all the arts, I mean also that it is the foundation of all the high virtues and faculties of men. . . . No great art ever rose on earth but among a nation of soldiers. There is no art among a shepherd people, if it remains at peace. There is no art among an agricultural people, if it remains at peace. Commerce is barely consistent with fine art, but cannot produce it. Manufacture is not only unable to produce it, but invariably destroys whatever seeds of it exist. There is no great art possible to a nation but that which is based on battle."

A NEW THERAPEUTIC FIELD

If in health, interest in one's work is essential, and adaptation of the work to the individual is a proper subject of study, how much more important to find rest for the enforced invalid through directed activity.

We have long been used to the idea of discipline through work, and of physical well-being through exercise, but it has remained for the vocational therapist to discover for us health through directed effort.

The Director of Occupation has chosen an important field, and one which involves initiative and a proper balance of therapy, psychology, and sociology.

The Arts as Adjuncts of Healing

Whether you agree with Ruskin or not, and he himself admits the inconsistencies of his reasoning on war[2], I am certain we shall all agree that out of this great war which has just ceased there has come a fine stimulus to the arts and the high virtues of men. That stimulus has been directed along numerous channels, not the least of which is in the development of the arts in the restoration of form and function to the human body. Never before have the arts, using the term in its broadest sense, contributed so largely to the service of medicine and surgery. In a more specialized sense "Arts and Crafts" have also become directly an indispensable adjunct of the art of healing.

This application of the arts and crafts we are calling occupational therapy. A lay-worker in the campaign against tuberculosis complained recently about the use of this term. "Why don't you," said he, "use a simpler term or explain what you mean." Let us then clear the ground for our discussion by defining occupational therapy. According to the Standard dictionary "therapeutics or therapy is the department of medical science that relates to the treatment and the action of remedial agents on the human organization, both in health and disease." The remedial agent may be drugs, water, climate, massage or exercises. My notion of occupational therapy is mental or physical activity definitely prescribed and guided for the specific purpose of contributing to and hastening recovery from the effects of disease or injury. Unless prescribed to promote recovery the activity is not therapy; indeed, unless wisely prescribed and properly guided it may contribute to death and not recovery.

The supervisor of reconstruction in one of the large army hospitals pointed out to me one of the cases of heart disease who was so absorbed in the task he was given that his face became livid. This supervisor seemed not at all to realize that the man was getting an over-dose of medicine just as surely as if he were made delirious by too great a dose of the tincture of digitalis.

Occupational therapy may be divided into three parts which are practically three stages in its remedial application:

1. Diversional therapy, in which simple amusements, such as games and puzzles, are used to occupy the fingers and divert the mind.
2. Occupational or handicraft therapy, in which definite tasks are assigned, involv-

*Read before the National Society for the Promotion of Occupational Therapy, at Hull House, Chicago, September 8, 1919.

[2] Ruskin, John: Notes on Political Economy of Prussia, dem.

ing the doing of useful things with woods, beads, textiles, clay, metals, etc., for the purpose not only of occupying the mind, but of assisting in the restoration of lost or weakened function.

3. Pre-vocational training, in which the prescribed remedial agents are employed for the distinct and studied purpose of leading up to definite education and training for some industry, trade, or profession.

Vocational education is a further stage in rehabilitation quite beyond the realm of therapeutics. Doctor Dunton points out in his excellent paper read before this society last year[3] that

This patient is learning the cobbler's trade and simultaneously, how to forget his troubles.

vocational education *per se* is not a form of occupational therapy, but he retains the term in his classification. It seems to me that the term "pre-vocational training" clears up the difficulty and makes a needed distinction between the third stage of occupational therapy and vocational education. It is needless to emphasize that the principles involved in the application of the arts and crafts to the restoration of function to injured muscles and tendons are entirely different from those involved in the treatment of mental diseases, and still different in the treatment of organic diseases. It is to the treatment of those suffering with tuberculosis that I would engage your attention for a time.

The supervisor of occupational aides in another of the army hospitals informed me that the aides who came to her were well grounded in the principles governing mental cases, but that none knew anything about the management of tuberculous people. Not a few of them were afraid to work among these cases. It will not be a digression, therefore, to refer to a few generally accepted facts regarding this most prevalent of all diseases and, next to injuries, the greatest cause of disability in the army. It is the more important that occupational therapists should realize the importance of studying tuberculosis, since the National Tuberculosis Association, in view of the results obtained in Army Sanatoriums, is beginning a very earnest study of the whole subject with a view to the wider introduction of occupational therapy to civilian institutions and for the purpose has added to its executive staff Mr. T. B. Kidner, one of the founders of this society.

Tuberculosis is an infectious disease that kills 145,000 persons in this country annually. The tubercle bacilli, the germs which cause the disease, are found most commonly in the sputum of those with active disease. They may be found occasionally in purulent discharges from other organs or parts of the body than the lungs.

Wood carving is an engrossing occupation requiring skill of eye and hand, while the pleasure taken in the development of the design assists in the cure of the patient.

Almost every adult at some time or other has become infected. That does not mean that every one has the disease, tuberculosis. It does mean that the germs have been sometimes and somewhere implanted in the body, and have so impressed themselves upon the organism that their presence can be detected by certain well established tests. Because the disease is not hereditary, new born infants do not respond to these tests. The conditions that surround them determine how long it will be before they become infected.

It has been generally believed that infection

[3] Dunton, W. R.: The Principles of Occupational Therapy, the Public Health Nurse, Dec., 1918.

Patients doing reed and raffia work in the occupational therapy department evolve some graceful designs in basketry

is most commonly acquired by the inhalation of the dust of dried and ground up sputum in the homes and on the streets. More recently, however, it is contended that infection is commoner by ingestion than by inhalation; germs being conveyed to the mouth upon the fingers of children who have been playing in contaminated places—the floors, sidewalks, gutters, etc., or with food handled by careless consumptives. Milk from tuberculous cows is also a not infrequent source of infection. But it cannot be too often emphasized that only the prolonged intimate association of healthy persons with those who have active tuberculosis leads to infection from person to person; and only among those with "open" disease, that is, in which germs are being discharged, is there any possibility of infection.

Infection vs. Disease

It is exceedingly important to keep in mind the distinction between tuberculous infection and tuberculous disease. Fishberg[1] and others contend that "mild infections with tuberculosis during childhood endow the organism with a certain amount of immunity against further and renewed infection with tubercle bacilli." There is no conclusive evidence that any physician, nurse, or attendant ever contracted tuberculosis in a well-conducted sanatorium. The careful consumptive is not a menace. He who guards his cough and destroys his sputum is safe to work with and safe to live with. It is the careless consumptive, and the one who does not know he has phthisis, who is dangerous, and he is most dangerous to children.

Gold medal exhibit of work done by patients of Arequipa Sanatorium Manor, and patients at work in Arequipa booth at Panama-Pacific International Exposition, San Francisco, in 1915.

This is an important point for all workers with the tuberculous, but especially for occupational therapists. Hitherto, in most training courses, stress has been laid chiefly upon the nature and characteristics of mental trouble for the relief of which, as you are aware, occupational therapy was first used; and precepts leading to a proper habit of thought towards patients suffering from

An exhibit of baskets and toys, the work of Muirdale patients in the industrial-recreation department.

mental troubles were enjoined upon the student in training. It is of prime importance that the mental attitude toward the tuberculous patient should also be correct and, to succeed in the work, the occupational therapist must free himself of every vestige of fear.

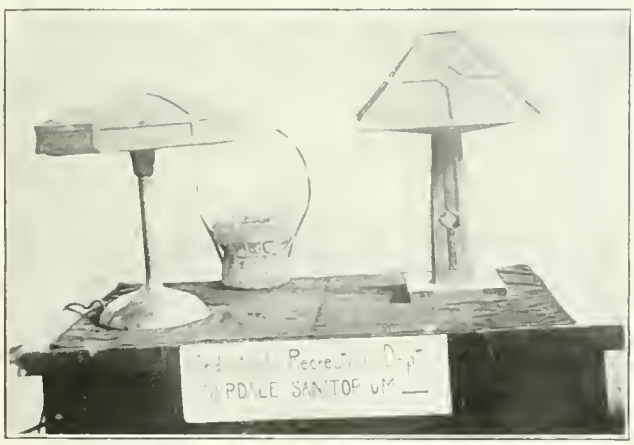
The recognized treatment of tuberculosis has become almost standard throughout the world. The purpose of treatment is the building up of the body, the healing of damaged tissues, and the walling in of the germs so that they may not be conveyed to other points to form new foci of destructive activity. There are no drugs, tuberculins, serums, or vaccines that will cure tuberculosis. Nature heals, and the patients help by securing rest, fresh air, proper and sufficient food, and by maintaining a sanguine and tranquil state of mind. It takes a long time to heal tissues that have been invaded and broken down by so insidious a foe as the tubercle bacillus. Many months and sometimes years are required to bring about permanent arrest of the disease.

[1] Fishberg, M.: Pulmonary Tuberculosis, Second Edition, p. 119. Lea & Febiger, 1919.

Psychologic Control Essential

The battle is a long and tedious one. It is a passive fight which is the hardest for previously active men and women to settle down to. New habits of life must be learned, a new self-control acquired. This is particularly difficult because of the psychologic state of many tuberculous patients. Hence the value of a period of treatment in a well conducted sanatorium which is more a school of life than a hospital.

Rest is of first importance. This sounds very simple but is less so than at first it appears. It involves not only physical passivity but mental quietude. One cannot rest who is having an exciting book read to him or who is worried by family or financial troubles. In the beginning of treatment it is generally necessary that the patient remain absolutely quiet in bed; it may be for a few days or several weeks.



Type of work done in the Industrial Recreation Department of the Muirdale Sanatorium, Wauwatosa, Wis.

Too much emphasis, however, has been placed upon muscular rest without due consideration of mental rest. It is quite impossible for some temperaments to lie still and not become mentally restless. Furthermore, as pointed out by Billings,[5] "adherence to the rest treatment is associated, in the average tuberculous patient, by lessened tone of the tissues, especially of the muscles, and by relatively poor circulation. Inadequate blood and lymph circulation means lessened nutrition of the tissues generally, although the weight of the patient may not indicate it. In other words, the patient's physical disease is much improved but the function of his mind and the circulatory and locomotive organs are far below the normal." Hence, there is an increasing trend toward the use of occupational therapy even while the patient is yet confined to his bed. The

[5] Billings, F.: Physical Reconstruction Applied in the Treatment of Pulmonary Tuberculosis. Transactions, National Tuberculosis Association, 1919.

As the workers become proficient in their occupational diversions more complicated tasks are assigned. This chest and table suggest manual training.

testimony as to its great value in managing tuberculosis among soldiers and sailors in the United States, Canada, and England is pronounced.

"One thinks of many things in bed," said a tuberculous woman. What those thoughts are may decide the patient's fate. Whether they are pleasant or unpleasant, hopeful or gloomy, or, rather, which shall predominate, depends upon the individual temperament and education, and upon environment. If the external stimuli to which the patient must react are not well ordered; if there is nothing to keep him from introspection, from magnifying his troubles, pondering upon his disease, speculating upon his symptoms and the prognosis, much of the value of physical rest will be lost.

Rest Obtained Through Activity

Occupation of the mind is often the best form of rest, and occupation of the hands is the means by which the mind may best be occupied. It is the use of the large skeletal muscles which tends to break down the tuberculous man, but those muscles are of less value in securing mental oc-

This outdoor, screened-in workroom offers an ideal place for Arequipa patients who choose to make pottery of the kind that wins international medals.

cupation. Their use has little cultural value unless the work performed is unusually varied and constructive in character. It is the smaller muscles that have distinct value in stimulating interest, imagination, and ambition. The hands trained to elicit harmony from the strings of harp or violin, that deftly weave a basket or shape the clay into artistic forms, that with square and compass make a constructive drawing, receive their impulses from an interested and developing mind. Curative work must be progressive and constructive. Miss Barringer has observed that the tuberculous soldiers in the army sanatorium at Oteen are themselves continually demanding higher standards of work. "Short of actual drudgery, the more useful the work the better its therapeutic results," writes Dr. Herbert Hall,[6] "and, conversely, the more trivial and

For those who are not bedridden, the occupational aide gives her instructions at a small table around which her student-patients are grouped.

valueless the product of the work, the less effective will it be in the therapeutic sense."

If the work given can be such that it will lead up gradually and naturally toward vocational training, or to vocation itself, so much the more is gained. Even when it is not believed that the patient will require training for a new vocation the "work prescription" should fit as nearly as possible his wishes and aptitudes, so that the knowledge gained may be employed in following an avocation. Some one has said that everybody should have two hobbies, one for indoors and one for outdoors.

In the rehabilitation of disabled soldiers two governmental agencies have been concerned, the Medical Department of the Army, and the Federal Board for Vocational Education. With the former have been the reconstruction aides, giving

Handicraft as taught in the United States General Hospital for Tuberculosis at Oteen, N. C., is not only a diversion but is a preparation for brighter times when health is restored.

the occupational therapy in the wards; also the more advanced work in the curative workshops under male instructors. With the latter have been the vocational advisers, who have counseled with the men as to their future training and placement. One group has had to do with restoration to health; the other, with restoration to industry. In the civilian institution there need not be, indeed cannot be, these two. Both functions must be combined in the director of occupation and his aides. This means a much broader field and, necessarily, a broader training equipment.

Guidance for Arrested Cases

The need for such service is very great indeed, particularly for the tuberculous. There is no more important problem confronting those grappling with tuberculosis than the post-sanatorium management of quiescent and arrested cases. Tuberculosis, as you know, is rarely cured in the sanatorium. There is always danger of reactivation of latent disease. Fifty per cent

Being forced to lie in bed does not necessitate idleness. Busy fingers accomplish wonders in this ward of the army hospital as the well-made and artistic cushion covers testify.

of patients discharged from our sanatoriums break down within a few months or a year or two. This is due largely to the fact that they go back to the very conditions in which their disease developed, conditions which will not permit them to live as they lived while under treatment. Having been under prolonged rest treatment, they are compelled by circumstances to return to full-time work. Often the work is wholly unsuited to their physical state; more often the conditions surrounding the particular job, rather than the work itself, are at fault.

The earning capacity of the patient should be the efficiency gauge by which to measure our service. Mere arrest of the disease is not sufficient. A man without symptoms of disease activity, but unable to work, is not worth much to himself and constitutes an economic drag upon the community. Restoration of social functions as a citizen is the final goal. To this end the physicians and the director of occupation must counsel with the patient.

Canadian soldiers being taught the art of clay modeling, bead weaving and kindred occupations while convalescing from tuberculous afflictions. (Photo by British & Colonial Press, Toronto.)

All vocational guidance has been said to involve four factors: (1) accurate vocational analysis; (2) wise vocational counsel; (3) adequate vocational training; and (4) correct vocational placement.

To counsel wisely there must be not only a knowledge of the processes in the particular industry under consideration but of what effect those processes may have on tuberculous disease in general and upon the particular patient. It must be determined whether the patient may return to his regular vocation; or whether he should be given training for a different job in the same general industry; or, yet again, whether he should be trained for an entirely new trade or profession.

DEPT OF SOLDIERS CIVIL RE ESTABLISHMENT

It is quite impossible to devise a list of suitable or unsuitable occupations for the tuberculous. A job in which one man could carry on successfully might be fatal to another.

There are few occupations indeed which may not be followed by some arrested cases. All cases can do something. Every case must be studied individually, and all the conditions surrounding the particular job must be studied carefully in order to form an approximately sound judgment as to the suitability of the job for the man.

Greenhouse work, for example, has always been looked upon as a splendid occupation for the tuberculous, but there may be two greenhouses side by side, built exactly alike, both used for growing rose bushes, and it will be found that one will be beneficial to the tuberculous and the other fatal. In one, the plants are being grown

Ward occupations such as these have been introduced in all the military hospitals in Canada. Weaving and reed work have the preference in this group. The work is being inspected by Sir James Lougheed, K. C. M. G., Minister,, Department of Soldiers' Civil Re-establishment. (Photo by British & Colonial Press, Toronto.)

for shipment and transplantation. They must undergo a hardening-up process. The temperature of the house is kept as low as possible, in winter from 55° to 60° F. In summer the plants are grown out of doors. The workers become sturdy along with the plants. In the other house the plants are forced for the purpose of supplying the cut flower market. The house is kept at a high temperature with a high per cent of humidity. The work is carried on under glass throughout the summer. That which favors the growth of rose blossoms likewise favors the growth of the tubercle bacilli.

Fallacy Misleads Many

There is no greater fallacy than the advice to tuberculous people to get "light outdoor employment." There is almost no such thing as a light outdoor job. If it is found it will also be discovered to return a light pay envelope. But good wages are necessary for the healthful maintenance of a tuberculous man and his dependents. The records of the Gaylord Farm Sanatorium[7] "showed that the factory workers held their condition distinctly better, and the office workers far better than did the outdoor workers."

The National Tuberculosis Association's Advisory Committee to the Federal Board for Vocational Education came to the conclusion that it was necessary to offer certain standards or factors to be considered in counseling with the tuberculous. Those adopted[8] are divided into four main groups, each with five subheads.

Personality and Working Conditions

The factors in Group I relate to the personality of the patient, (1) his present health, particularly as to the amount of damage done by the disease processes, and the degree of arrest shown by the medical records; (2) temperament and education, for it is necessary to know whether he is "high strung or phlegmatic, stupid or quick of perception, and the extent of his education and training"; (3) his hopes and ambitions must be taken into account; (4) age will have a direct bearing on vocational education and (5) the sex of the patient must be considered, both for training and placement.

Group II comprises the factors due to conditions of work. (1) Is it active or sedentary in character; indoors or outdoors; heavy or light; involved or simple? (2) Attitude and position are important, for any work requiring a continuous stooping or strained position would be unsuitable. (3) Time, duration, and pauses: is it to be day or night work? It must not be seasonal, requiring intensive application at certain times of the year. Speeding up is dangerous. Tuberculous people should not work more than eight hours daily; some must work less. (4) Fatigue, tension, and responsibility; lifting of heavy weights, and vigorous exertion of the upper extremities must be avoided. Continued nerve strain and too much responsibility are dangerous. (5) Are wages on the *per diem* or piece work basis, and are they adequate for the patient's needs?

Group III comprises factors due to materials and processes; the kind and quantity of (1) dusts; (2) poisons; (3) gases and fumes; (4) infectious material; (5) dangerous machinery and appliances.

Group IV comprises the factors involved in the place of work. (1) Tuberculous cases should not work in high winds nor under a burning sun, nor in slush and rain, nor in super-heated shops. (2) The construction of the work place: flooring is an important item. Basements, underground areas, and overcrowded shops should be avoided. (3) Air: ventilation, temperature, and humidity; (4) light and illumination; (5) sanitary comforts must all be considered.

Having determined what seems to be the wisest course for the patient to pursue, the occupational therapist should cooperate with all existing outside agencies in securing vocational training or proper employment for the patient when his disease becomes arrested. If it be possible to relate the work provided during the treatment to the patients' training or occupation after the disease has become arrested, we may be sure that, as pointed out earlier in this paper, its therapeutic value will be increased manyfold.

A Specialized Profession

I shall have failed in my purpose in presenting this paper if I have not visualized to your mind's eye opportunities for a constantly broadening service, a very real specialized profession for which, fostered by this society, the Federal Board for Vocational Education and the National Tuberculosis Association, there will be a growing demand. For the men and women entering this profession there must be a title and standards of training and of salary. In a recent publication by the New York City Department of Health[9] the occupational therapist is called the "Supervising Orderly." The term "orderly" has long connoted

[7] Lyman, D. R.: Following up the Discharged Sanatorium Patient, American Review of Tuberculosis, Dec., 1918.

[8] Pattison, H. A.: Treatment and Training for the Tuberculous. Bulletin 29, Federal Board for Vocational Education.

[9] Slade, C. B.: The Establishment and Conduct of a Tuberculosis Sanatorium, N. Y. City Dept. of Health: Monograph Series, No. 19, Dec., 1918.

certain very necessary hospital duties not even remotely related to occupational therapy, but coming under the jurisdiction of the head nurse. The occupational therapist must be directly responsible to the medical director and might himself be a physician. Such a title, therefore, as supervising orderly must not be permitted to gain currency, for it is altogether beneath the dignity of your calling. I like the title "Director of Occupation" used by our president in his new book.[10]

[10] Dunton, W. R.: Reconstruction Therapy, W. B. Saunders Co., 1919.

Assistants might be called occupational or vocational aides or advisers.

High qualities of mind and heart are required for the wise management of those who are ill mentally or physically. Permit me to suggest, however, that academic requirements should not be too high, nor the course of training too long. Not men and women with just so many years of high school or college credits are needed for occupational therapy, so much as men and women with common sense, with love of humanity, and with capacity for mental and spiritual growth.

MEDICAL SERVICE OF ILLINOIS STATE INSTITUTIONS UNDER NEW CODE

By A. L. BOWEN, Superintendent of Charities, Department of Public Welfare, Springfield, Ill.

THE reorganization of the executive branch of the Illinois state government under the provisions of the Lowden civil administrative code took place on July 1, 1917. Among the nine state departments which came into being that day was the Department of Public Welfare, created to administer the state's charitable and penal institutions and to perform all the functions formerly performed by the Board of Pardons and Parole. The code created in this department seven subdivisions as follows: assistant director, fiscal supervisor, superintendent of charities, alienist, superintendent of prisons, criminologist, and superintendent of pardons and parole.

The Civil Administrative Code of the State of Illinois possesses the admirable qualification of elasticity. It states general principles and leaves to the director of each department the organization of details and the formulation of policies.

This foresighted provision has made possible the steady advancement of the medical, nursing, social service, occupational therapy, and research work in the charitable and penal institutions of the state, under the direction of the Department of Public Welfare. Staffs in state hospitals have been enlarged, and the State Psychopathic Institutes for special training of physicians has been established.

The civil administrative code possesses the admirable qualification of elasticity. It states general principles and leaves to the director of each department the organization of details and the formulation of policies.

Prior to July 1, 1917, the state charitable institutions, including the hospitals for mental diseases, had been administered by a Board of Control of five members of whom one was an alienist, by whom the first steps had been taken in the development of a comprehensive medical service in these nineteen big institutions. Staffs in state hospitals had been enlarged; a state psychopathic institute for special training of physicians in nervous and mental diseases had been organized; a training school for nurses in each state hospital had been raised to a good standard.

But the alienist of the Board of Control was a dual purpose officer and was handicapped by restrictions, inherent in the plan of organization, which he could not overcome. The prisons, prior to July 1, 1917, were not under unified control. Each went its own way, more or less influenced by political expediency, giving no attention to the medical, psychologic, or psychiatric problems, so numerous among their inmates. The new code brought these two classes of institutions, charitable and penal, into one group to be administered by a single head with the advice and executive help of division heads.

Dr. H. Douglas Singer, for many years director of the State Psychopathic Institute, was chosen as alienist and he was made the head of the medical and nursing service of the charitable institutions. He acts in the capacity of a staff officer, or adviser, the administrative details being cared for by the Superintendent of Charities.

For Criminologist, Dr. Herman M. Adler, formerly assistant director of the Boston Psychopathic Hospital and a member of the faculty of Harvard Medical School, was selected to bear a

similar relation to the penal institutions, acting in an advisory or staff capacity to the Superintendent of Prisons and Superintendent of Paroles.

To the two men was assigned the task of developing the medical, nursing, social service, occupational therapy, and all research work of the department to the very highest standards possible. The war period, which depleted the existing staffs and rendered recruiting impossible, delayed their work; but their plans were laid and are now well on the way to completion.

Material Gains Achieved

Among the results actually achieved may be mentioned:

(1) A working agreement between the state Department of Public Welfare and the University of Illinois Medical School for the creation of a great central group of hospitals for research. Two squares, formerly the Chicago National League ball park, south of the Cook County Hospital in Chicago have been purchased, and soon work will begin on the construction of buildings to house the Illinois Charitable Eye and Ear Infirmary, now located at 900 West Adams street, Chicago; the State Psychopathic Hospital and Institute, the nucleus of which is now at the Chicago State Hospital; and the Surgical Institute for Crippled Children, created a few years ago but never vitalized by an appropriation. These three institutions are contributed by the Department of Public Welfare. The medical school will build a clinical hospital. One and a half million dollars are available to begin this work. Architects have finished the block plan and are now working on detailed plans so that construction may begin in the spring.

Future plans call for a number of other hospitals and institutions and the removal of the college laboratories to new buildings on this site. The Department will administer the group and the university will furnish the professional service.

Included in the functions of this group will be the state training schools for psychiatric nurses, social workers, occupational therapists, and hydrotherapists, the department having established the policy of training its own specialists for its institutions.

(2) The organization at the Chicago State Hospital of the Illinois State Training School for Psychiatric Nursing under the superintendency of Miss Helen Sinclair. This school furnishes a three year course. Pupils must be high school graduates. Affiliation has been established for mutual benefit between this school and general hospital training schools. Graduates will be eligible to the ranks of psychiatric nurse, psychiatric supervisor, assistant chief nurse, and chief nurse, all well compensated positions.

Pertaining to Personnel

(3) The medical staffs of the state hospitals have been increased 40 per cent in number and salaries have been increased by twenty-five dollars per month.

(4) A state surgeon to do the surgery in all institutions, not provided with a surgeon, on their staffs, has been appointed and is at work.

(5) The position of assistant chief nurse has been created for each state hospital.

(6) The practice of the specialties in each institution is being organized so that among the insane and feeble-minded in particular, it is planned to give eye, ear, nose, and throat treatment on extensive basis.

(7) Full-time dentistry has been established in each large institution.

(8) A training school for qualified nurses, not eligible to registration, has been organized in each state hospital.

(9) Two new institutions, the Alton State Hospital and the Dixon State Colony for Epileptics, have been organized and opened since July 1, 1917, in the face of war conditions which made it almost impossible to secure help of any kind. The first now has 700 patients and the second 300. Appropriations are available to increase the former to 1,200 and the latter to 1,000 patients.

(10) Vacancies among medical superintendents have been filled by promotion from the rank of assistant superintendent, thus removing the last vestige of politics from the state charitable institutions.

(11) Among the institutions for children, such as the schools for the deaf and blind and the home for dependents, marked progress has been made in furnishing special care and treatment of medical and surgical character.

Occupational Therapy Organized

(12) Occupational therapy on the broadest basis yet laid in a state hospital service in this country is being organized in all state hospitals, beginning in Chicago and Elgin, where students for positions in the army received their training and experience. Appropriations are available at all the state hospitals for the inauguration of this work on an extensive scale. The handicap is the lack of teachers and workers. Mrs. Eleanor Slagle, probably the leading woman in this profession in this country, is general superintendent of the work for all the Illinois institutions.

(13) The last legislature made liberal allow-

ances for the organization of comprehensive social work in all hospitals and other institutions. This work is to be under the direction of the alienist and criminologist. Workers are being installed as fast as they can be secured. The state is being districted. Each district will be in charge of a chief worker and such assistants as she may need. Each state hospital will have a resident social worker. The district organization will serve the needs of all the institutions which may be represented in the population of the district, and will act in harmony with the resident social workers of the state. Already some very gratifying results have been secured from the work of these trained people.

(14) On the side of the Criminologist the first steps have been taken in the organization of a real medical psychologic and psychiatric service in the prisons and the two schools for delinquents, located at Geneva and St. Charles. The Criminologist's division is furnishing the division of paroles with studies of prisoners who are about eligible for parole. Complete survey of the boys in the reformatory is in progress under expert direction.

(15) The Criminologist has organized and has in running order in Chicago, the State Juvenile Psychopathic Institute which is seeing and advising hundreds of families and individuals. It cooperates with the county court of Cook County in the determination of cases involving feeblemindedness.

Summed up, the organization of the medical forces under the state Department of Public Welfare conforms to the following lines:

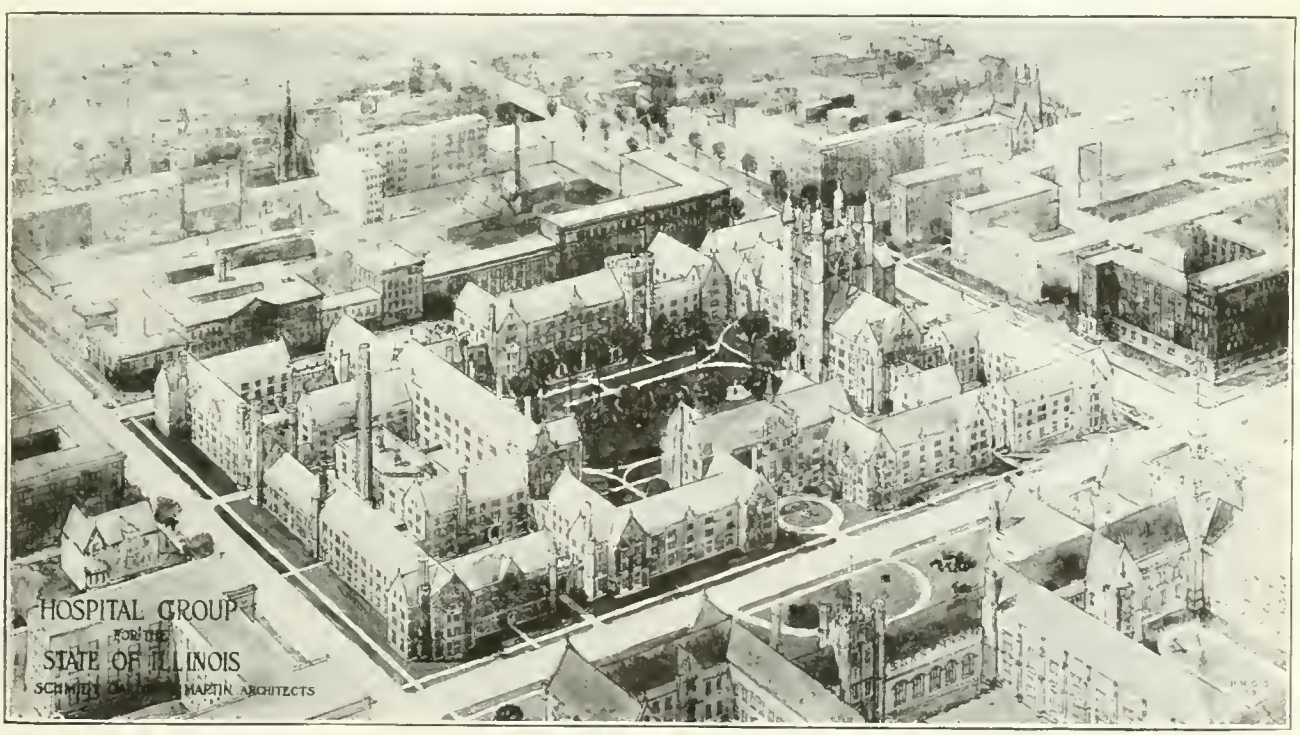
I. General Medical Service

The general medical service affords ordinary medical and surgical care for the charitable and penal institutions. Physicians are recruited by civil service on whole or part time as necessary. No promotion is possible.

II. Special Psychiatric Service

Special psychiatric service for the insane hospitals, feeble-minded schools, the epileptic colony, and penal and correctional institutions. Men are recruited through civil service, preferably after serving an internship in a state hospital. A man in this service begins as assistant physician, with promotion to physician, and then to one of two lines according to the direction of interests. One of these is administrative to assistant managing officer from whose ranks in the main managing officers are selected, the other in more professional line leads to appointment as assistant psychiatrist and psychiatrist. Physicians especially interested in pathological work can also be placed as pathologists in the state hospitals and rank with the physicians.

Assignments to duty may be made either in insane hospitals or in the penal and correctional institutions, and thus afford the possibility of developing special interests. Opportunities in the



Birdseye view of proposed new group of hospitals which will furnish the clinical material for the University Medical School. Buildings will be erected on site just south of the Cook County Hospital.

latter field are especially good at the present time.

Opportunities for instruction of these various officers afforded from time to time through courses given by the Psychopathic Institute will be increased by the establishment of out-patient clinics in mental and nervous diseases in connection with the educational service, with the various state hospitals, and also in correctional work through the Juvenile Psychopathic Institute.

At the present time psychiatrists and assistant psychiatrists report direct to the Criminologist or Alienist and work, assigned in the Juvenile Psychopathic Institute, in the Psychopathic Institute, and in the penal and correctional institutions. The assistant managing officers, physicians, and assistant physicians report to the managing officer of the institution to which they are assigned.

III. The Educational Service

The educational service includes psychiatry and the specialties of the eye, ear, nose and throat work, as well as orthopedic service. This educational service, which will also constitute a special research service, is supplied by the medical college of the University of Illinois through the several departments interested. Special service for interns in state hospitals with provision for instruction in psychiatry during part of their service in the central group of education hospitals about to be erected is offered. This is not limited to students of the University of Illinois College of Medicine.

The Psychopathic and Juvenile Psychopathic Institutes will form part of the educational group and arrangements will be made to afford instruction and opportunity for research to psychiatric officers of the state hospitals and penal institutions. The professional work of the Eye and Ear Infirmary and of the Orthopedic Hospital will be directly under the College of Medicine of the University. Special provisions are at present made for the care of major surgical cases by the appointment of an institutional surgeon who visits the various hospitals. Cases needing special surgical care can be transferred to one hospital which has been equipped for the purpose. This service will eventually center in the educational group.

University Educational Campaign

A press bulletin service by means of which the larger newspapers in Illinois will be furnished with news stories and articles pertaining to public health, hygiene, and sanitation, has been inaugurated by the department of hygiene and public health of the University of Illinois. The articles are contributed by members of the faculty who are authorities on the various branches of health work. The movement is part of the public health education work of the university.

The Late Sir William Osler

Sir William Osler, noted physician and author, whose death occurred at his home in Nordham Gardens, Oxford, Eng., December 29, after a long illness. For the past fifteen years he had been regius professor of medicine at Oxford. Prior to 1904 he was professor of medicine at the University of Pennsylvania, and at the Johns Hopkins University, Baltimore.

GOVERNMENT CONTINUES WELFARE WORK

All welfare work previously done in army camps and cantonments has been taken over by the military authorities. At the request of the surgeon general, the Y. W. C. A. will maintain its social directors in army hospitals until such time as the army can provide funds necessary for carrying on this work.

ISSUES WEEKLY HEALTH INDEX

Weekly mortality reports from the largest cities in the United States are being issued as a health index by the Bureau of the Census. Special attention is called to the figures supplied by the industrial insurance companies and published at the bottom of the last page of the reports. These data furnish each week a valuable index of mortality for comparison with the rates in cities of 100,000.

PLAN HEALTH CONSERVATION

A plan for nation-wide conservation of health is being urged by Surgeon General Blue, of the United States Public Health Service, who is calling on all the health agencies to cooperate in a carefully prepared program. In the statement just issued he says that preventable disease cost the United States $4,000,000,000 less in 1917 than it would had health conditions of twenty years ago prevailed in 1917. Illness of workers still costs this country $2,000,000,000 a year.

A NEW POLICY

THIS department of MODERN MEDICINE will from the present issue enter a new policy. The collaboration of the staff of departmental editors will make it possible for us to publish a much wider range of material than has heretofore been possible.

We believe that this department of MODERN MEDICINE has a particular function to perform. It will attempt to present month by month all of the important publications in various fields in medicine and it will constantly aim to present its material from the standpoint of the general medical reader rather than from the point of view of the specialist. Furthermore, the editors will take the liberty of inserting in the body of their reviews editorial comment. It is assumed that the specialistic reader obtains his special literature from particular journals devoted to that purpose. It is, however, difficult for the average man of medicine to-day critically to estimate the value to general medicine of many articles published in the specialistic journals. Men who are doing intensive work can more readily appraise publications and, perhaps, even see their relative values better than anyone else.

The editors in all modesty realize that in adopting such a policy they adopt an attitude of critical ability which in the nature of human affairs may not be present, but we feel that it is a far wiser effort at constructive medicine to add the human comment than to bring before our readers the cold facts. If the readers do not agree with the comments, they can at least feel sure that an honest effort will be made each month to present them with the more important medical contributions culled by a large number of readers from the extensive literature of the day.—EDITOR.

LACK OF SUNLIGHT AS A CAUSE OF ANEMIA

AS our modern industrial life grows in complexity an ever increasing number of human beings find themselves in occupations in which they labor for a considerable number of hours each day entirely cut off from the rays of the sun. Formerly the miners made up probably a majority of those so occupied, but more recently our large cities with their miles of "subways" and the basements and sub-basements of our metropolitan "sky scrapers" have created myriads of new subterranean workers. Now there has always been a distinct belief both among laymen and physicians that a lack of sunlight leads to anemia and, if this be true, we are facing a socio-medical problem of no little importance. With the aim of gaining some experimental data towards establishing the truth or falsity of this generally accepted idea Grober and Sempell[1] have conducted a series of observations on horses working in the coal mines of Westphalia. These animals had lived continuously underground for from five to ten years, had received excellent care in the way of food, drink, cleanliness, etc., and appeared in every way in fine condition. Determinations were made on the blood of twenty-two of

[1] Grober and Sempell: Composition of the Blood After Prolonged Withdrawal of Sunlight, Deutsch. Arch. f. clin. Med., cxxix, 5-6.

these animals as to the per cent of hemoglobin and the number of erythrocytes. Compared with the results obtained from healthy horses living on the surface of the ground, it was found that the blood of the mine animals showed an increase of about 12 per cent in the red cells and a slight diminution in hemoglobin. The depth below the surface at which the mine animals worked was not a factor in the results since the readings from animals living on different levels were fairly uniform and in the same direction. Evidently, then, long continued lack of sunlight causes no anemia in well nourished and well cared for horses.

While it would be wrong to draw from these experiments any very certain conclusions as to the effect of lack of sunlight on the blood of human beings it might be well to discard our preconceived ideas on the subject and to attempt by properly controlled observations to gain some insight into this important problem.—(J. E. C.)

A RECONSIDERATION OF CARDIAC AFFECTIONS

WE are so accustomed to read stereotyped classifications in medical literature that it is a novelty to find an article that deviates from the accepted "truths," and expresses new ideas regarding some disease. For many years the medical literature clung to a classification of heart diseases based on the presence or absence of murmur and the location of same. It is hard to find a single textbook that does not divide chronic valvular diseases into mitral regurgitation, mitral stenosis, double mitral, aortic regurgitation, and aortic stenosis. In view of this, it is interesting to read the article by Thomas Lewis on cardinal principles in cardiological practice.[1] In this article Lewis has reconsidered the classification and conception of heart diseases. He points out that the old classification is only of minor value for a guiding prognosis or therapy, that a systolic murmur over the precordium tells little or nothing of a man's capacity for work, and that the term "double murmur" is a misnomer. The author is of the opinion that in dealing with chronic heart affections there are but two conditions of the aortic and mitral valves, which will repay a general physician expenditure of much time and thought; these are incompetence of the aortic valves, and stenosis of the mitral valves. Both these conditions may usually be diagnosed with confidence, for it is their habit to present signs of an unequivocal nature. That is of high importance; a step taken with certainty is of far greater value than one taken even a little less confidently. A prognosis is too important a thing to mould on anything but a secure basis.

After discussing briefly the important symptoms and signs of cardiac failure, of cardiac enlargement, or valvular disease, and of fibrillation of the auricles, the author reaches a point where he not only criticizes, but also advises. He says:

> There is a direction in which medical men are much hampered in dealing with chronic heart disease. It is in trying to order the future lives of working class men to suit the heart's power of reserve. Many cardiac patients leave our hospital wards after a short period of rest, a period during which there has been much improvement of the heart's capacity for work. Yet these patients are but too often totally unfit to take up again those daily tasks in and by which they have already suffered. To tell a working class man that his former work suits him ill, to tell him that he must find new work of lighter grade, is good enough advice; but how often is it within the man's power to act on that advice? How often is it within the doctor's power to see that his advice is followed? We greatly need in this country a system by which disabled workers are placed and cared for in suitable employment. Cardiac cases are for the most part conspicuously willing workers, frequently too willing; there are many men doing heavy work in this country to-day, and at the same time surely, but may be slowly, dying of heart disease. It is a shameful thing that these unfortunates are put by hard necessity to tasks far beyond their endurance.

The above advice, given to medical men in England, can well be taken by medical men in this country. The cardiac problem in this country is just as acute as in any other country, and it behooves every physician who comes in contact with a heart case to think not only of the proper grouping of the patient's condition, but also of the prognosis, and of the treatment with the hope of solving, in some degree at least, the problem of that particular patient.

ON SUGAR, CHOLESTEROL, URIC ACID, AND ALBUMIN

THE increasing amount of study which has been devoted to the above mentioned subjects has by no means as yet succeeded in clearing many of the mysteries of the interrelationships between blood chemistry, disease, and renal excretion.

There still remains to be painted a picture such as we now posses regarding red blood cells or white blood cells in their relation to various diseases. There is no dearth of literature on these subjects, and to-day we pick at random a few of the recent contributions.

Hamman[1] writes on the significance of a small amount of sugar in the urine. He says that on

1. Hamman, Louis: The Significance of a Small Amount of Sugar in the Urine, Carad. Med. Assn. Jour., 1919, ix, 961.

the discovery of a small amount of sugar in the urine the physician is confronted with the question, what is the meaning of this discovery? Three possibilities arise: (1) mild diabetes, (2) "an interesting but innocent abnormality," and (3) neither one nor the other, but an unknown something requiring further investigation. In order to determine to which class the patient belongs there must be a definite means of separation.

Hamman gives the best known means of differentiating these groups. He lays special emphasis on the proper method of collecting urine. It is a well known fact that glycosuria even in a diabetic will sometimes appear only after a meal containing carbohydrates and that the morning urine may be sugar-free. It is, therefore, unwise simply to ask a patient to bring a specimen of urine without designating that such specimen should consist of the urine voided from two or three hours after the heaviest meal of the day, as well as the morning specimen which he will naturally bring. As has been previously emphasized by many other writers, the mere reduction of copper sulphate solution is not proof of glucose, and the urine must be further studied to identify the substance by the fermentation test or perhaps by more extensive chemical work.

Hamman then discusses the modern conception regarding blood sugar and shows the differences between the blood reaction in a true metabolic disease and that in a renal anomaly after the ingestion of a known weighed amount of glucose. A metabolic disturbance is characterized usually by a somewhat prolonged rise in the level of the blood sugar associated with glycosuria. (It should be emphasized, however, that there may be mild degrees of diabetes which are not orthodox in their reaction.[2])

Mention is made of an interesting anomaly which is beginning to occupy more and more attention since the first case was published by us in American literature in 1914, namely, renal glycosuria. This is a disease which is characterized by the continued excretion of small amounts of sugar without hyperglycemia and with none of the clinical symptoms of diabetes. The necessity for laying stress on this condition lies in the established fact that diabetic treatment is contraindicated and that these patients get along better when left alone.[3]

In the same journal Mackay[4] reports a case of postural albuminuria in a young man twenty-seven years of age. This case had all the characteristic manifestations of this interesting anomaly, namely, presence of albumin practically only when the patient was in a standing position, and its disappearance on rest and after exercise. In Mackay's case the Mosenthal renal function meal gave a perfectly normal reaction and the phthalein excretion was 62 per cent in two hours. These postural albuminurias are still the subject of much investigation, but it is very probable that they do not represent a condition of true nephritis, and from the standpoint of treatment need not be considered as such.

Rothschild and Felsen[5] discuss the cholesterol content of the blood in various hepatic conditions. They review previous work in the study of cholelithiasis in which a group of patients was encountered who had a continuous hypercholesterinemia, which persisted even after operation and the removal of obstruction. It was thought from the previous work that the liver was the regulator of the cholesterol metabolism of the body. In the present study, however, it was found that in conditions associated with hepatic disorders the cholesterol content of the blood is not increased, and is usually reduced; and that the cholesterinemia is not proportionate to the amount of bile pigments present in the blood. Also, in the so-called hemolytic icterus there is no increase of blood cholesterol.

These two findings are in direct contrast to the previous observation that in obstructive jaundice due to stones the cholesterol content of the blood bears a definite relationship to the intensity of the jaundice.

Upham and Higley[6] publish a study of the renal concentration power for uric acid in early chronic interstitial nephritis. Patients were placed on a diet containing 2,880 calories and with known amounts of food constituents for forty-eight hours previous to the examination of the blood and urine. The concentration ability of the patient is measured by dividing the amount of urine uric acid by the amount of blood uric acid, the authors believing that this figure is of greater value than the blood uric acid alone.

From their study of nephritic and non-nephritic cases, they make three clinical groups: (1) A group showing clinical symptoms of nephritis. In these patients the concentration figure is 14 or lower. (2) A group with no clinical symptoms of nephritis and a concentration figure of 20 or above. (3) A group which shows clinical symp-

toms suggestive but not diagnostic of nephritis with a concentration figure below 18.4.

Only thirty-four cases were studied altogether, and in the opinion of the editor the conclusions, while interesting, are by no means more than suggestive. In order to get the proper chemical values from a study of this kind, it seems to us that a large series of patients must be used and that the diagnosis must be broader than one based merely on kidney lesions. It hardly seems logical to suppose that the kidney is the only factor in the complex uric acid metabolism even when considering merely its concentration.

ETIOLOGY OF YELLOW FEVER

THE recent work of Noguchi, of the Rockefeller Institute for Medical Research, on the Etiology of Yellow Fever, published in the June to October numbers of the *Journal of Experimental Medicine*, conclusively demonstrates the causative agent of Yellow Fever. It is important to recall at this time the work of Reed, Carroll, Lazear, and Agramonte, which was published in 1899 and 1902. They were the first to show that Yellow Fever is not a bacterial disease; that it is conveyed by one species of mosquito, *Stegomyia faseiata Seu Calopus*, from person to person; that an incubation period is necessary in the mosquito of from ten to twelve days before its bite is infectious; that the disease can be transmitted directly by injecting blood from a patient on the second or third day of the disease into a nonimmune, and that the virus of Yellow Fever can be passed through a Berkefeld or Chamberland filter. This important work was done by an American commission and can be considered as having been completed by Noguchi, working in an American laboratory.

Guided by the researches of Reed, Carroll, and their associates, Gorgas, by means of exterminating most of the mosquitoes, and by protection against them, has virtually done away with Yellow Fever in Havana and in the Canal Zone, Panama. This entire work is one of America's greatest contributions to medicine.

Since the pioneer work of Reed, Carroll, and their associates, there has been no important contribution in the study of Yellow Fever previous to the present work of Noguchi. This work should be read in the original properly to be appreciated, for it is a model as a systematic, concise, simple statement of a tremendous discovery.

The first article gives a remarkably clear picture of Yellow Fever as it occurred in Guayaquil. This demonstrates the identity of the Yellow Fever in Guayaquil with the disease as it is recognized elsewhere, and there can therefore be no doubt that the disease studied was Yellow Fever. The description of the disease in Guayaquil should be of great interest to clinicians.

The second article presents the "Transmission Experiments on Yellow Fever" and confirms the previous findings of the Reed-Carroll commission as to transmissibility, the relationship of the mosquito to transmission, and the filterability of the virus.

The third paper deals with the symptomatology and pathological findings in animals experimentally infected. Noguchi states that "the symptoms and lesions observed in animals experimentally infected closely parallel those of human Yellow Fever." The pathological changes occurring in the experimental disease are also similar to those of the human disease.

Article six describes the cultivation, morphology, virulence, and biological properties of the causative agent of Yellow Fever. The method of cultivation is a modification of Noguchi's original method for the cultivation of spirochetes and also of the globoid bodies of poliomyelitis. This special method of cultivation has already yielded remarkable results in the hands of Noguchi and many others, and is probably the most important contribution to bacteriological technic in the last twenty years.

The original method of Noguchi is as follows: In a tall culture tube, about 1x20 cc. in size, is placed a small piece of sterile rabbit kidney; a column of ascitic fluid 8 to 10 cc. high is then added and, after inoculation, the medium is overlaid with a layer of sterile paraffin oil or vaselin. It would seem that the ability of the sterile kidney tissue to absorb oxygen and render the conditions in the serum almost completely anaërobic is one of the important elements of the media. A modification of these media is used by Noguchi in the work on Yellow Fever. These tubes were inoculated with citrated blood drawn from the patient or infected animals. A great many tubes were inoculated and in some of them an organism belonging to the genus *Leptospira* was found in from three to five days, by both dark field and staining methods. This organism has been tentatively named *Leptospira icteroides*. It has been isolated in pure culture and successfully transplanted. When pure cultures are inoculated in the guinea pig and some other animals, the typical experimental disease develops. This is identical with the disease which develops when blood from a patient is inoculated and the same organisms are recovered from the blood of the infected animals. The presence of blood serum is essential for its growth. It passes through the pores of a

Berkefeld filter and N., and there is a possibility of its having a granular phase of life under certain conditions.

The organism is somewhat similar in appearance to the *Leptospira icterohaemorrhagiae* of infectious jaundice. It has, however, definite morphological differences from the latter organism, as well as biological and immunity differences. The *Leptospira icteroides* has been demonstrated in the blood and urine of Yellow Fever patients during life, and, also, in their tissues after death, as well as in animals experimentally infected.

Article eight deals with the presence of *Leptospira* in wild animals, in Guayaquil, and its relation to *Leptospira icterohaemorrhagiae* and *Leptospira icteroides.*

Article nine is an extremely interesting study of the relationship of mosquitoes to Yellow Fever, confirming the work of Reed and Carroll, with the addition of the isolation of *Leptospira icteroides* from animals infected by the bites of mosquitoes.

The importance of this contribution of Noguchi's can scarcely be overestimated. Although Yellow Fever is not present in the world today in the epidemic form in which it formerly occurred, it is nevertheless of the greatest importance to know the organism which is the cause of this disease. The importance of the relationship, or rather the differentiation, between the cause of Yellow Fever and Infectious Jaundice is only one of the accessory facts already brought to light by this investigation. Probably the fact of greatest significance brought out by this work is the value of the newer bacteriological methods of Noguchi in studying the disease Yellow Fever, which we previously knew was caused by a filterable virus. These methods should be intensively used in studying other infectious diseases whose etiology is unknown.—W. T.

PROPHYLAXIS AND TREATMENT OF TETANUS

THE knowledge and treatment of the disease of tetanus gained through war experience can be bodily transported into civilian practice. Although most of the individual facts were known, the subject as a whole was not widely understood.

It was anticipated that the incidence of tetanus among the wounded, fighting over territory heavily fertilized for centuries, would be very high. Due to the prophylactic treatment it was, on the contrary, very low. It was soon recognized that the initial dose of 500 to 1,500 units of anti-tetanic serum immunized the patient for a comparatively short time.[1] The British concluded this time to be about two weeks (ten days). After this the patient could be infected from his own wound. Therefore, it soon became the practice to repeat administration of the anti-tetanic serum after an interval of a week, usually using about 500 units.[2] The period of a week would place the second dosage within the limit of the immunity and also within the limit of an anaphylactic reaction. The dosage was repeated weekly as long as the condition of the wound made it appear likely that a re-infection might occur. Wounds which were constantly being contaminated by feces, such as wounds of the rectum or colon; large, evidently septic wounds; or wounds in which there still remained bits of clothing,—foreign bodies,—were looked upon as probable foci for infection.

Long before our troops got into action the custom of very early and very complete wound débridement (through excision by necrotic tissue, removal of foreign bodies, etc.), had been universally adopted. This of course was invaluable in lowering the tetanus incidence.

In spite of the repeated doses of prophylactic anti-tetanic serum, late secondary operations for reducing deformities, overcoming contractures, or bone operations in site of the original wound, were followed by tetanus. As a rule, this type was more benign than the usual case, but many serious cases also developed. It became apparent that the tetanus organism, probably in its spore form, was very resistant to all forms of treatment; it remained dormant for long periods of time, and could be aroused into activity by operative manipulations.[3] For this reason, before any operative procedure on an old wound a dose of 500 units of A. T. S. (anti-tetanic serum) was given. The serum was given in the concentrated form, usually into the muscles of the abdomen, although the thigh, buttocks, and other muscular parts could be used as well. No particular effort was made to inject in or near the wound.

Wherever the above mentioned method of prophylaxis was faithfully carried out, the incidence of tetanus, as previously stated, was exceedingly low.

Tetanus which did develop after the prophylactic treatment, developed atypically.[4] Trismus was very often absent. With many cases the symp-

4. Lumiére, A.: Sur le tëtanos post-sérique, Ann. de l'Inst. Pasteur, Paris, 1917, xxxi, 19.

toms were confined to localized muscle groups, where rigidity, increase in reflex irritability, or a subsultus was noticed. The dictum that the longer the incubation period the milder the tetanus held good to a certain extent.[5] Attendants, nurses, and orderlies were directed to report such signs as increased nervousness of the patient, slight rigidity of the neck or certain muscle groups, slight paralyses, or an increase in reflex activity, all of which were regarded as possible signs and symptoms of tetanus. Treatment was begun at the very earliest possible moment. Large doses, often 50,000 units of A. T. S. were given within the first twenty-four hours. The intramuscular method was found to be the safest and best. The serum was more readily absorbed than when given by the subcutaneous route, and in all but the most serious cases the system could be quickly enough flooded when large doses were injected into the muscles. The intravenous and intraspinous, or intrathecal injections were found to have a field of usefulness in very severe cases. Magnesium sulphate injections were discarded by most of the authors.[6] After tetanus had once developed, surgery was found to be of very little benefit. Associated with the antitoxin treatment, must be emphasized the insistence of absolute quiet and rest.

CHICAGO CLINICS FOR MALNOURISHED CHILDREN

By BLANCHE M. JOSEPH, Field Dietitian, Emmanuel Mandel Memorial, Michael Reese Dispensary, Chicago, Ill.

The work of dietitians as an adjunct to health centers, out-patient departments of the various hospitals, and dispensaries in Chicago, has long pointed to malnutrition in children as a problem calling for a specific program in which all agencies need to unite. The insight into prevailing conditions in Chicago of Mrs. Ira Couch Wood, representing the McCormick Memorial Fund, made it possible to secure Dr. Wm. R. P. Emerson, of Boston, Mass., who, with the assistance of Miss Mabel Skilton as chemical nutrition worker, began the work with two weeks of intensive training in malnutrition.

The first week gave to a group of physicians, nurses, dietitians, and social workers a course evolved in the nutrition classes held by Doctor Emerson in Boston. The second week was devoted to lectures, illustrated by lantern slides, which visualized to the student, parent, and the community the malnourished child as he is found in the congested districts and boulevards of the city.

To disseminate as far as possible the interest in the malnourished child, Doctor Emerson spoke before many people in various parts of Chicago, reaching in this way teachers' clubs, parent-teacher associations, the Pediatric Society, and the Chicago Medical Society, as well as the various women's clubs. Demonstration clinics were held daily in the public schools. As a result of this intensive work, Chicago is ready for the job. Every agency is ready to help. During the next few weeks dispensaries will open clinics for the malnourished child, the school child, and those unable to get working certificates on account of under weight.

That this is a civic problem is shown by the fact that 25 per cent of the children in the United States are malnourished. Try as hard as they may to master the three R's, these under-nourished children find their work too great for their strength, and they need special clinics to be brought into normal growing condition.

The first preliminary to the work of the clinic is a complete physical examination. When the physical examination shows a child to be in condition to be admitted to a nutrition class, he is then free to gain. With the correction of his faulty health and food habits he increases in weight with great rapidity. The routine in each case involves, (1) the removal as far as possible of existing physical defects, (2) the home control of nutrition conditions, (3) the removal of any condition of over-fatigue, (4) the correction of improper food habits, and (5) the detection of any improper health habits. If a child is of marked under weight or is not gaining at the normal rate, the reason for the situation is then disclosed. It is not to be regarded as hereditary or unimportant.

Even if without special care a child reacts finally from conditions due to malnutrition, he may in the meantime form bad mental habits; his power to think quickly may be impaired; or he may become more susceptible to diseases than the normal child. The element of over-fatigue plays an important rôle. Too many movies, too many outside attractions, clubs, parties, and advanced studies are bad for the malnourished child, and he must be given more frequent rest periods. Children that are "finicky" about food must be understood and taught the proper habits of eating, regular meals, and no candy between meals. Coffee and tea are forbidden.

It is remarkable to see how quickly the child gets the "I will" spirit, and in class exercise with other children competition plays a great part. Charts are kept of each child's progress. They watch their line charts as the children move up the line of "Proper Weight for Height" and they feel if their neighbor "malnourished friend" can gain, they, too, will live up to the letter as the doctor prescribes. A marked change is noted in the appearance, and the gloomy, inactive child becomes alert.

The work of the clinic is supplemented by intensive class work in the schools and dispensaries under the guidance of a physician who is making this a special study. Follow-up work is done by a nutritional worker who fills in the picture of home environment and other contributing conditions.

The ultimate result of this form of medical service should certainly advance the physical standards of this generation and the next. In it we have the promise of healthy men and women who more nearly conform to the standards of weight and height. A final report of the work will be made in the pages of MODERN MEDICINE at the conclusion of the classes.

WILL STUDY AT STATE INSTITUTION

A small class of graduate students of the Massachusetts College of Pharmacy will spend one day each week during the first half of the session at the State Anti-Toxin Laboratory at Forest Hills. The work will be on vaccines, serums, and the like. During the last half of the year the class will study physiological testing.

STANDARDS OF PUBLIC MATERNITY CARE
A COLLECTIVE ABSTRACT

By HUGO EHRENFEST, M.D., St. Louis, Mo.

THE Children's Bureau of the United States Department of Labor has just published Section III[1] of the *Standards of Child Welfare*. This pamphlet contains a large number of papers dealing with "The Health of Children and Mothers" presented in a series of regional conferences which had been arranged in various cities by the specially created Child Welfare Department. In submitting these reports Miss Julia Lathrop, the chief of the Children's Bureau, in a preface points to the fact that obviously the views of method and approach expressed by the various contributors are at variance, but that as a whole there is a marked agreement on the great essentials of a child welfare policy for the Nation. These essentials are: Public responsibility for the growing generation; confidence in constructive measures; insistence upon greater uniformity in laws; and upon the necessity of enlisting able and devoted citizens to carry on both public and private child welfare activities. "Under circumstances of such difficulty as we happily can not conceive, the civilian population of Europe was achieving new laws for the protection of childhood, new ideals for the future development of the race. It was felt that the second year of the war in the United States ought to show a popular sense of responsibility for child welfare in some degree commensurate with our opportunities."

A Proper Obstetric Service

Williams[2] lays down the following standard requirements for proper obstetric care applicable for all larger cities: (1) Monthly prenatal visits during the second half of pregnancy, with examination of the urine. (2) A careful preliminary examination four or six weeks before the expected date of confinement, which should include a general physical examination, as well as pelvimetry, mapping out the position of the child, and the determination of the existence of any serious disproportion between the size of the head and the pelvis. (3) Reasonable care at the time of delivery by one who will observe the ordinary rules of aseptic technic and who knows enough to abstain from meddlesome midwifery, with the understanding that suitable hospital accommodations are available for all patients presenting such complications as can not be satisfactorily treated in their homes. (4) A careful postpartum examination four weeks after the birth of the child, for the purpose of relieving or treating minor abnormalities, and of detecting the existence of such lesions of the birth canal as may require operative relief. (5) Supervision of the baby for the year following its birth.

Difficulties in Rural Districts

Under present conditions such standards unfortunately could not be maintained in many rural districts, for in many such localities physicians are not available, and the woman is often fortunate if she can obtain the services of even a partially trained midwife.

Progress in this regard can be made only along three lines: By a campaign of education in which the women and their husbands are taught that it is their right and duty to demand reasonable care during pregnancy and at the time of labor; by the institution of state aid and by national subventions, partly for educational purposes, but particularly for the carrying out of such minimal standards as seem essential; and by legislation requiring local health officers or midwives,—in localities where they are generally employed,—to assume charge of the situation and to lay down certain regulations which the midwives must be compelled to follow.

The first step in such a campaign would consist in the compulsory registration of every pregnancy through the local health officer. It then will be possible to furnish every pregnant woman with certain instructive literature and to help her to provide proper care at the time of labor. Midwives would be permitted to take charge only of cases found normal on examination, and should be required by law, even in cases certified as presumably normal, to call a physician whenever labor lasts more than twenty-four hours, or when any unexpected abnormality develops. Women presenting abnormalities at the time of registration should be directly referred to a physician or hospital.

The adoption of such regulations obviously

[2] Williams, J. Whitridge: Standard Requirements for Obstetrical Care, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

would necessitate a revolution in the methods of medical practice in rural districts, and could be carried out only if sufficient funds were available.

Venereal Problem in Welfare Work

The importance of the venereal problem in child welfare work is taken up by Jeans,[3] who especially emphasizes the known seriousness of syphilis. He calls for the routine Wassermann test as an essential in a good standard of prenatal care. According to his figures, the waste in infant and child life in a large group of syphilitic families is more than 60 per cent as compared to less than 25 per cent in a similar group of non-syphilitic families of the same social plane. He found that statistics from four cities of this country indicate that about 10 per cent of married pregnant women are actively syphilitic as shown by the Wassermann reaction. Statistical studies made in St. Louis and New York show that among the poorer classes from 5 to 6 per cent of the infant population are syphilitic. Surely such figures would prove an alarming prevalence of syphilis, and, therefore, it may be stated that in discussing this paper, Doctor Baker, of the Health Department of New York City, emphasizes that, judging from the number of deaths from syphilis among children within the first year of life, Doctor Jeans' figures are entirely contrary to New York experiences.

The Control of Midwifery

Chapin[4] discusses the ever present problem of the control of midwifery. The midwife is not indigenous, surely not in a manufacturing center; she comes with the recent foreign immigrants. Medical practitioners in general, and obstetricians in particular, denounce the midwife; social workers and public health nurses do not like her; and health officers do not consider her an asset to the community. The latter, however, while desirous of replacing her by something better, admit that she is not so inimical to public health as are many physicians. In some cities the midwives report births and cases of ophthalmia with greater promptitude than do the physicians.

For the prevention of infant mortality prompt returns are essential. There are many physicians who know little about infant feeding; their babies die, and the health officer can do nothing about it. The midwife is more likely to send her babies to the welfare station, where they are cared for by specialists. As a whole, therefore, the midwife can not be considered a direct hindrance to the prevention of infant mortality. In knowledge, the midwife must always be far below the physician and it is a safe deduction that she is not an institution to be fostered, but is rather to be tolerated only until such time as an acceptable substitute can be found. We allow non-medical individuals to provide glasses for our eyes and to attend women in confinement, but do not permit anything like it in any other specialty.

An Invidious Comparison

However, when a serious comparison is made between the results of midwives' practice and that of physicians, it is at times apparently unfavorable to the latter. A few years ago Williams aroused great interest in his argument that poor doctors have more deaths against them than have the midwives, and that there are many poor doctors. The majority of teaching obstetricians were of his opinion. Doctor Baker says that the morbidity and mortality, both of mothers and babies, at least in New York, are greater among those attended by physicians than among those attended by midwives. Dr. Van Ingen has presented figures, relating to the lower East Side of New York, which show that stillbirths are much more frequent in the practice of physicians than in the practice of midwives. The great fallacy of such statistics, of course, lies in the selection of cases. Difficult confinements gravitate to the physician or the hospital, while the normal cases remain with the midwife.

There are several reasons why there is a demand for midwives. They are cheaper. Many foreign women do not want a male attendant or, what is more probable, their husbands do not wish it. This is a custom or fashion that should not prove very difficult to change. In this process of education the public health nurse will be called upon to play an important rôle. The last important reason for the employment of a midwife can be found in the fact that she will incidentally also perform more or less of the household service.

In general, evidence shows that midwifery is decreasing, probably chiefly as the result of an increasing appreciation of good medical service.

Suggested Means of Control

Various plans have been adopted, or proposed, for solving the midwife problem. Some states by statute laws absolutely forbid her practice, but none of them has made a serious attempt to enforce the law or to drive out the midwife. Another plan, which may be developed in different ways, is to license the midwife. Such licensing may amount to a mere registration, with refusal of registration if the midwife prove careless or

[4] Chapin, Chas. V.: Control of Midwifery, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

incompetent, or it may develop into a more elaborate system under which registration would be made dependent upon definite education, training, examination, and subsequent supervision. This latter system has been adopted in some of the eastern states.[5]

If midwives are to be supplanted, the offered substitute must appeal to the patrons as desirable. If, therefore, the midwife is to be supplanted by the physician, the latter must not cost more than the former, and the supplanting process surely will be more rapid if he does not cost as much. A free out-patient service certainly draws cases from the midwife. Wherever there is a medical school, such service is necessary for teaching purposes. Even if the patient is able to pay a midwife, it must be considered legitimate to draw her away from the midwife by free treatment. Thus at the Boston Lying-in Hospital the out-patients contributed in 1918 on the average $1.38 each, which was an appreciable help in meeting the low cost of the service.

That such a service pays from a public health standpoint is shown by the fact that maternal mortality in the last 5,000 out-patients was 0.04 per cent. That this low rate was not secured by sending an undue number of difficult labor cases into the hospital is indicated by the low mortality of 1.1 per cent among the house cases in the same year. Where there are no medical students available, an out-door service is best provided in connection with a maternity hospital. The country certainly needs a much larger maternity service, which can be and should be added to general hospitals. The utilization of a resident staff for out-door obstetric work makes for efficiency, as the work can be supervised by the hospital management and the service is sure to be more prompt and regular.

Patients on Part Pay Basis

The "pay clinic" has, for various types of service, been strongly advocated in Boston as a means of securing efficient treatment for a class of persons who can pay only a moderate sum, but yet sufficient in the aggregate to afford modest compensation to the physician. The Maverick Dispensary in East Boston makes a charge of $15, the usual fee of the midwife, and of this $10 goes to the physician. The physicians are men who are glad temporarily to take this service to perfect themselves in obstetrics. In discussing this paper Doctor Levy, of the State Board of Health of New Jersey, agrees that under regulation and supervision the adopted standards are better maintained by midwives than by doctors. Furthermore, he feels that obstetricians should not fear the existence of the midwife in perpetuity. "Elevating her status is a sly way to eliminate her, because as you elevate her standard she demands more for her services, and this must bring her finally in competition with the physician. By the law of the survival of the fittest, if the doctor is a superior individual, he will finally survive." A similar view is expressed by Doctor Baker who states that in New York by the constant supervision of the midwife, and the elimination of those who violate regulations, the number of practising midwives in ten years has been reduced from 3,000 to 1,600. "Midwives are a condition and not a theory. It is essential to remember that poor people who have to deal with them are guided by practical considerations rather than by academic theories."

Maternity Care in Foreign Countries

The essentials for public care of maternity and infancy in England are explained in a paper contributed by Mrs. Eleanor Barton,[6] representing the Women's Cooperative Guild of England, which Guild for several years has given special attention to this work. In the preparation of the General Insurance Act they insisted on the inclusion of maternity benefits, and, agitating public opinion by a literary propaganda, they had a maternity act passed by the House of Parliament in 1918. Under this Act a maternity benefit of thirty shillings for each child is given to the wives of men who are insured and come under the income tax limit. The women who go out to work, if they themselves are insured, receive benefits in their own rights, thus making a double maternity benefit. An attempt is made further to improve the situation by bringing the whole question of maternity under the Ministry of Relief now in process of formation. Bad housing and sanitation are responsible for much suffering, but ignorance and the absence of medical advice and help are also responsible.

It is vital to the welfare of all countries that an enlightened and generous care of maternity should replace the present indifference and neglect. There are many people who say to-day, "Yes, the husband and father should provide in this way. But this is not correct, not enough. We want the public service. After all, the child is the asset of the nation; and we want the nation to recognize that the welfare of the child is its business. During the war when the State wanted the boys they put their hands on their shoulders and took them, without any questions being

[6] Barton, Mrs. Eleanor: Essentials of Public Care of Maternity and Infancy, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

asked. Now we want the State to realize that it is responsible in exactly the same way for its children. The question now is whether better service can be had by communal service, or leaving it to the individual. It seems that the individual service has broken down completely, and now we want to put in its place municipal and national service." The whole question of maternity should be placed under national supervision, so that every woman can receive expert maternity care, and nobody shall ask whether she is rich or poor.

The horrible situation among the Serbian population is vividly pictured by Doctor Lazarevitch.[7] Among them the question of child welfare is a most urgent one. There are at present in Serbia 100,000 invalids, 100,000 children in need of immediate care, and 50,000 orphans. These are the numbers in a country which out of a population of 4,500,000 during the war has sustained a loss of 1,330,925 who died from disease or were killed. "Notwithstanding the fact that our people are very strong and healthy, bad hygienic conditions exist and ignorance of the fundamental rules for the proper care of the expectant mother and the baby prevails. The State, which has been obliged to buy guns and munitions to insure its very existence, has had neither the time nor the money to devote to hygienic conditions and the care of the mother and the baby." The new United Kingdom of the Serbs, Croats, and Slovenes, on February 5, 1919, created a state Department of Child Welfare.

Welfare Work in Cities

The urban problems of prenatal care are discussed also by Doctor Helmholz,[8] of Chicago. It seems that at the present time the larger cities of this country entirely neglect this side of infant welfare. Experience shows that in the prenatal work one nurse can attend to approximately three hundred pregnant women; in postnatal work she can care for about one-half of this number in the course of a year. The chief requirement consists in adequate hospital facilities for all difficult cases and an ample obstetric outdoor service to care for the mothers who remain at home. While the close coordination between the prenatal and obstetric work is important, still more vital to the welfare of the infants is constant and uninterrupted supervision immediately after birth. In Chicago, in spite of all efforts, more than two-thirds of all babies come under the care of the Infant Welfare Society over two months old. As the death rate is the highest during the first month of life, the postnatal work still is missing this most important period of the infant's life. In speaking of the artificial food question the author expresses as his opinion that in the not very distant future powdered milk will in a large measure replace all fresh milk because it is safer and cheaper. Also, the housing question needs more attention. The public has not as yet been educated up to the importance of this factor in its relationship to infant mortality.

Lobenstine[9] describes the maternity centers in New York. Never before have nations been brought to such a keen realization of the value of the mother and her child. With the frightful losses at the front, with the startling ravages of the world plague continually before us, and with the inevitable injuries wrought in the home by the strenous efforts of the war, conservation of the infant's life stands out as the pressing need of the hour. Childbearing still possesses for the mothers many dangers, some of which are avoidable, and some of which are not; but this we know definitely, that the closer the supervision during pregnancy and the better the care at the time of delivery, the fewer will be the complications and the more satisfactory will be the results. The number of partial and complete invalids as the result of poor nursing, inefficient medical attention, or meddlesome midwifery at the time of abortions or labor, can not be estimated.

The Danger in the Life Span

The studies carried on by the Federal Children's Bureau, as well as by certain public and private organizations all strikingly reveal the fact that "the nine months of intrauterine life coupled with the first month after birth represent the high mark of danger in the life span of every individual." With properly organized clinics one could expect a reduction of from 30 to 35 per cent in the deaths under one month, a material lowering in the number of stillbirths, a reduction in premature births of at least 25 per cent, and in the maternal death rate of from 60 to 65 per cent below the general rate of unsupervised cases. This conservation movement is a great social undertaking. It is a fight against poverty, filth, rum, tuberculosis, and ignorance of the barest fundamentals of health.

New York City began two years ago to develop a plan for the coordination and extension of maternity care among the poor. After a thorough study of the distribution problem a zoning system was designed. At present the borough is divided

[7] Lazarevitch, Dr. Radmilla Milochevetch: Serbian Experience, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.
[8] Helmholz, Dr. Henry F.: Urban Problems, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.
[9] Lobenstine, Dr. R. W.: Maternity Centers in New York City, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

into ten zones. The districting has many advantages. The hospitals draw their patients from their particular zone, rendering prenatal supervision of the registered cases far easier. It encourages patients to seek hospital aid more readily because of their greater familiarity with the hospital in their own neighborhood. The hospital forms the basis for the entire maternity center plan. A maternity center should be the center of an educational campaign for the prenatal care of the mothers in the district, and the fathers should not be neglected. The chief point in the whole scheme is a good follow-up system. The doctors and midwives in the district must be urged to bring their cases to these clinics for consultation. They should be open day and night for emergency calls; they should see that a doctor or midwife is supplied for every labor case, and a nurse for every abnormal labor. In the discussion, the Boston idea of better medical service for the middle classes is emphasized by Mr. William Lowell Putnam. The people of moderate means are the people who are least cared for in the matter of protection of the health of mothers and infants. For the past five years an attempt has been made in Boston to bring this care within the reach of those mothers who can not afford the prices required by the best physicians, and yet who should not be offered charity, and who under no conditions would be willing to accept it.

The Needs of the Rural Mother

Obviously, as pointed out by Miss Elizabeth G. Fox[10] of the American Red Cross, the rural mother is in need of this same prenatal, natal, and postnatal care offered the city mother. However, it is quite one thing to outline these essentials, and quite another to provide them. In the rural problem one of the chief difficulties is the inaccessibility of medical care. Many country women simply have to do without medical supervision, entirely relying on their own resources and the help of neighbors. Many country people also are unable, or unwilling to pay the cost of good medical care. They have not yet learned to regard childbirth as a serious and important event. Many country doctors are not informed concerning the best obstetric practice. Normal cases under such circumstances usually survive this amateur assistance, but abnormal cases suffer a high injury and death rate. Many counties and communities have not as yet installed a public health nursing service. If well developed, such service could be made to include prenatal, natal, and postnatal care.

Another foe, usually more beforehand than the doctor or the nurse can be, is the patent medicine vendor. Finally, behind all these difficulties lies the ignorance or indifference of the farmer and his wife. The rapid development of rural public-health service offers one of the most immediate and tangible remedies. Adequate obstetrical service will have to be placed within the reach of all, through health insurance, mothers' pensions, some form of state aid, or else through a more just distribution of the profits of labor. Cottage hospitals or county maternity hospitals are necessary for the proper care of complicated cases. The Red Cross through its plan to promote rural health nursing hopes to contribute toward the protection of maternity and infancy in this country.

Dr. Julius Levy, of the New Jersey State Board of Health, adds that it is important to realize that the real solution of the rural problem lies in the responsibility of the state department of health. The most worth while effort of the Red Cross or any other organization is merely to insist that the state department of health shall perform its proper function in protecting the health of the rural population, and that the function of private institutions is not to do in piecemeal the things that are needed in rural communities.

British Control of Midwifery

In describing British organization Sir Arthur Newsholme[11] explains the working of the Midwives Act of 1902, whose provisions have been enlarged and rectified by the Maternity and Child Welfare Act, passed in August, 1918. "Although we have enjoined upon local authorities the necessity of the strictest economy in public expenditures, we have urged increased activity in work which has for its object the preservation of infant life and health. We are glad to note that the great majority of local authorities have realized the value of continuing and extending their efforts for child welfare at this time." A beginning in grants for child welfare work was made by the Board of Education for the establishment of schools for mothers, and similar institutions in which collective instructions to mothers was given and some degree of regularity of attendance of the mothers was secured.

In 1914 the Local Government Board sent a circular letter and covering memorandum by their Medical Officer which may be claimed to have initiated maternity and child welfare work on a larger scale, more generally distributed throughout the country, and more completely covering

[10] Fox, Miss Elizabeth G.: Rural Problems, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

[11] Newsholme, Sir Arthur: British Organization, s. 1, Pub. 60, U. S. Dept. of Labor, Children's Bureau, Washington, D. C.

the whole sphere of medical and hygienic work for this purpose than had previously been envisaged. The chief burden of the additional work to which local authorities were urged was that there should be continuity in dealing with the whole period from before birth until the time when the child entered upon a school register. The memorandum contemplated that medical advice and, where necessary, treatment should be continuous and systematically available for all expectant mothers and for children till they enter school, and that arrangements should be made for home visitation throughout this period.

Grants were promised to local authorities or to voluntary agencies for work done under this scheme amounting to one-half of the total approved expenditure. About the same time a circular was sent out by the Board of Education promising similar grants for schools for mothers. The increased work since that date can be seen in the fact that while in the financial year 1914-15 the grants of the Local Government Board amounted to approximately £11,500, and of the Board of Education to not quite £11,000, they had reached in the financial year 1917-18 the sums of over £122,000 and £24,000, respectively, while they were estimated for the next year as £209,000 for the Local Government Board, and £44,000 for the Board of Education.

These grants do not cover the entire scope of child welfare work for England. Thus, for instance, the Ministry of Munitions took an active part in arranging for welfare work in the establishments for which it was responsible, and this work in some instances included special care for pregnant women and for nursing mothers.

At the conclusion of these conferences of the U. S. Child Welfare Department committees were appointed to formulate minimum standards in regard to children entering employment, for the protection of the health of children and mothers, and for the protection of children in need of special care.

Minimum Requirements for Protection

A subcommittee proposed the following minimum requirements for the public protection of maternity:

1. Maternity or prenatal centers, sufficient to provide for all cases not receiving prenatal supervision from private physicians. The work of such a center should include:

(1) Complete physical examination by a physician as early in pregnancy as possible, including examination of heart, lungs, abdomen, urine, and the taking of blood pressure; internal examination and pelvic measurements before the seventh month in primipara; examination of urine every four weeks during early months, at least every two weeks after sixth month, and more frequently if indicated; Wassermann test when indicated.

(2) Instruction in hygiene of maternity, and supervision throughout pregnancy, through at least monthly visits to a maternity center until end of sixth month, and every two weeks thereafter. Literature to be given mother to acquaint her with the principles of infant hygiene.

(3) Employment of sufficient number of public health nurses to do home visiting and to give instruction to expectant mothers in hygiene of pregnancy and early infancy; to make visits and to care for patient in puerperium; and to see that every infant is referred to an infant welfare center.

(4) Confinement at home by a physician or a properly trained and qualified attendant, or in a hospital.

(5) Nursing service at home at the time of confinement and during the lying-in period, or hospital care.

(6) Daily visits through fifth day, and at least two other visits during second week by physician or nurse from maternity center.

(7) At least ten days' rest in bed after a normal delivery, with sufficient household service to allow mother to recuperate.

(8) Examination by physician before discharge of patient, not later than six weeks after delivery.

2. Clinics, such as dental and venereal clinics, for needed treatment during pregnancy.
3. Maternity hospitals, or maternity wards in general hospitals, sufficient to provide care in all complicated cases and for all women wishing hospital care; free or part payment obstetrical care to be provided in every necessitous case at home or in a hospital.
4. All midwives to be required by law to show adequate training, and to be licensed and supervised.
5. Training and registration of household attendants to care, under the supervision of physician or public health nurse, for sickness in the home and for the home during sickness.
6. Education of the general public as to the problems presented by maternal and infant mortality and their solution.

WILL MIDWIVES GRADUALLY DISAPPEAR?

From one-third to one-half of births in Chicago are attended by midwives, according to estimates of members of the Chicago Medical Society who have appointed a committee to cooperate with the state department of registration and education. Since 1917, when the registration of midwives was first required by law, there have been

3,281 licenses issued in Illinois, and it is estimated that more than 500 are practising in Chicago. In 1915, half the births registered were registered by midwives. Medical men are divided in their opinion as to whether or not more training and educational facilities should be offered midwives, or whether lack of such assistance will assist in the processes automatically working for the disappearance of the midwife.

THE PRACTITIONER'S DIET NUMBERS

The reviewer would require the Shavian method were he to do full justice to the July and August, 1919, numbers of the *Practitioner*, London, which are devoted to diet in health and disease. As an expression of British nationalism and British methods the two volumes are even more interesting than they are as indicators of the British scientific thought on the subjects discussed. The July number is devoted entirely to diet in health, and, though the student of dietetics finds in it many things with which he does not agree, he nevertheless must recognize the broad clinical experience and the sound judgment which form the basis for all the papers. It is rather interesting to find milk condemned and idealized as a perfect food in different pages of the same magazine.

Part I. Diet in Health

In the introduction the editor advances a plea for the use of more uncooked foods, allowing the imagination to range back to the dietetic habits of primeval man when cooking was unknown to man. Cookery became a fashion because of its "gustatory allurements . . . and it is in the increased and thus unnatural palatability of cooked foods that we must seek for part, at any rate, of the explanation of habitual over-eating." Cooking, also, probably affects the composition of foods.

Professor W. M. Bayless gives a brief review of the physiology of nutrition. Emphasis is laid upon the fact that for most people a greater quantity of protein is desirable than a minimum actually necessary, a point which has previously been emphasized by Graham Lusk. Bayless, also, recalls that protein should be of mixed origin, especially when being used by the growing organism, because of the variations in the amino-acid content of the different proteins. "Although both protein and carbohydrate are necessary, it is at present impossible to make the same statement with certainty in respect to fat. There is, however, no doubt that it is desirable, if only for the preparation of attractive dishes by the cook." The 3,300 calorie diet per man of 70 kilos which is recommended by the Royal Society Committee contains:

	Grams	Calories	Per Cent
Protein	70	280	8.5
Fat	90	810	25
Carbohydrate	550	2200	67

This, incidentally, differs from the American army proportion of 14, 31, and 55 per cent, respectively.

Parkinson's contribution on dietetics in childhood and youth contains many unproved statements regarding what is good and bad for children. For instance, the list of foods which should never be given to children under six years contains the following: pork, ham, sausage, tinned foods, goose, duck, game, etc.; cucumbers, radishes, tomatoes, and raw celery; hot new bread and cakes containing dried fruits; nuts or any kind of pastry; bananas. The reviewer knows of no scientific basis for the inclusion of nuts, raw celery, tomatoes, or ham in a list of harmful foods.

"Dietetics in Adolescence," by Clement Dukes, is a really remarkable clinical contribution, which suggests that "the roast beef of old England is largely responsible for the well known stamina of the Anglo-Saxon race and the winning of the war." Ultra-scientists might object to the phrase "carbohydrates in the form of fat and sugar" or to the conception of nature converting food into lymphocytes; but the man dealing with the feeding of young people will get much of practical value from reading every word of this article. Milk is a standard food for those in process of growth and should continue being given largely during youth.

The amount of nourishment required by the growing organism is great and "stinting is synonymous with stunting. In the case of the girls whose growth between the ages of 11 and 16 is amazing, stinting of food essentials amounts to positive cruelty, and they are apt to suffer throughout life for this serious defect. They are sometimes told that it is unladylike to eat much, whereas, they should be counseled that it is their bounden duty to eat as much and as varied wholesome food as they can possibly command, so that they may develop as Nature purposed." Adequate feeding of the young is the cheapest policy, and two essentials are adequate knowledge by the caterer and personal supervision. Monotony of food must he done away with, especially in feeding groups. It is only too easy to over-feed the adult, but superabundant nourishment is almost impossible in those rapidly growing, provided, of course, the food is not rich in quality. Sufficient time must be allowed for meals and special consideration given to the slow eaters. The main food supply is desirable in the early part of the day.

The staple articles of diet for adolescents are bread, of which the whole meal breads are more suitable although less palatable; butter, which, of course, is a standard food. Oatmeal porridge is ideal for adolescents because of all cereals it contains the largest percentage of protein, fats, and mineral substances. Sugar and starch should furnish a large part of the diet. Fresh milk must always be an integral part of the diet of the adolescent. "It is more than thirty years since I prevailed upon that great Head-master of Rugby, John Percival, late Bishop of Hereford, to substitute, in place of beer, an equal quantity of milk at supper, with untold value to this renowned school from every point of view."

In this connection it may be recalled that the American dietary is deficient in milk, which is especially true among the relatively poor who do not appreciate comparative food values. Meat should be given twice a day to adolescents, at breakfast and mid-day dinner, but should not be given later in the day; and a daily quantity should average one pound of uncooked meat, including fat. Soup is beneficial, mainly because it furnishes the vehicle for vegetables and cereals. Fat is an absolute necessity, especially in the form of milk, butter, bacon, and suet pudding. The vegetables, although difficult to feed to adolescents, are essential to prevent malnutrition. Fruits serve the same purpose, but are better liked. The diet, likewise, must not be lacking in mineral salts. Cheese is wholesome for adolescence. Alcohol should be conspicuous by its absence. The chief cause of indigestion in healthy adolescence arises from drinking tea or coffee too strong, too much, or too frequently. Water must be given frequently.

Charles Mercier discusses dietetics in senescence. "Less is known about dietetics than about any other department of physiology, and if anything is known of the modifications of diet that are desirable in senescence, it is not known to me." Yet he gives a rather convincing argument for a diet containing rather less amounts of car-

bohydrate and fat and greater amount of protein than is usually recommended to the man growing old. In fact, Mercier goes so far as to suggest that the man who cuts down his ration of protein below an ill defined minimum will invariably suffer from inefficiency and confusion of mind; and if the deficiency is great enough and is continued long enough, will land himself in a lunatic asylum. "No weight of beefsteak will turn a dullard into a genius; but a man cannot attain or maintain his intellectual best without an ample ration of protein. . . . The beverages appropriate to on-coming old age are alcohol in its various preparations, tea, and coffee. Water is a perilous beverage for anyone, but especially for those whose resistance to the attacks of microörganisms is beginning to fail along with their other powers. Alcohol has its dangers, no doubt, but they are nothing in comparison with the dangers of drinking water."

Dietetics in old age is treated by Thomas Bodley Scott, and Campbell contributes some general observations on diet, the first of which is that milk in any form is not necessary for the weaned child.

Lieut. Col. S. Wright discusses the dietary of troops in the home army during the war, which contains nothing that was not discussed in the last number of this journal.

Part II. Diet in Disease

Diet in acute disease is treated by Sir John F. H. Broadbent. This article starts with an eulogy of milk as the most suitable diet in acute disease. The body of the argument does not agree entirely with the American conception so well worked out by Warren Coleman, and one misses a discussion of the high caloric diet in typhoid fever. Broadbent mentions that a more liberal diet may be of little risk, but believes that the fluid diet, of which milk forms the basis, is the most suitable.

W. Langdon Brown discusses the dietetics of diabetes and glycosuria and reviews in an excellent manner the newer methods of treatment based on the studies of Allen in this country and Graham in England. The diabetic "must be permanently under-fed to avoid overtaxing his damaged powers of assimilation. Clearly the outlook depends upon how much these powers are damaged. If he can balance his metabolism, when the caloric food is adequate to maintain life and a fair display of energy, the outlook is good; if he cannot acquire a balance until the intake is reduced too much for this, the outlook is bad, for there must be a limit to this process of reduction."

The statistics from the newer treatment of diabetes quoted by Brown are interesting. Formerly, at Guy's Hospital, 16.9 per cent of the cases were fatal during the first year of the disease; but now only 5.4 per cent. Formerly, the average mortality rate was 23 per cent of all cases admitted; now; it is 7.7 per cent. By the older methods only 9.8 per cent were rendered free from sugar, even for a single day; now, 73.5 per cent are rendered free for a longer or shorter period. Brown doubts Poulton's conclusion that a patient who is treated within three months of the onset has a 75 per cent chance of being kept sugar-free indefinitely.

Leonard Williams writes on diet in obesity and, although the searcher for practical menus to give his patient finds nothing in this article, he will find a fascinatingly written plea for the use of uncooked foods.

Dietetics in chronic arthritis is written by F. G. Thomson, and the discussion is based on the assumption that rheumatoid arthritis, synovitis, fibrositis, gout and osteo-arthritis are all closely connected with intestinal infections and intestinal stasis. "To sum up, the diet in rheumatoid arthritis should consist of light, simple, easily digested food, strictly limited to such quantities as the patient can digest. In severe cases, and those which do not improve on this régime, the total exclusion of meat may be advisable; whereas in others, especially those with symptoms of gastric ulcer, or such as are intolerant of starch, a diet consisting chiefly of eggs, milk, milk puddings, custard, and the like, may be carefully tried. The inclusion of vitamins is essential, and a certain amount of raw fruit, salad, eggs, milk, and other vitamin-containing food should never be omitted. In cases in which it assists digestion, a reasonable amount of stimulant may be allowed. Apart from assisting in this way, it will do no good nor, so far as one can see, does it do any harm."

In fibrositis the indications for diet are the same as in rheumatoid arthritis and in osteo-arthritis; the two objects of diet should be the promotion of a healthy condition of the gastro-intestinal tract and a diminution of the tendency to corpulence. "The diet should consist chiefly of fish, poultry, game, and the lighter kinds of meat; eggs, fruit, salads, green vegetables, junket, and cheese. Bread must be replaced by dry toast, rusks, or dry, unsweetened biscuits. Puddings and pastry should be entirely eliminated."

P. Bergouigan writes exceedingly well and clearly on the diet in renal and circulatory diseases, giving practically all that is known in a succinct and easily readable manner. The classification of renal disease adopted is that of Widal and Castaigne; (1) acute nephritis, in which a strict milk diet is an absolute necessity; (2) simple chronic albuminous nephritis, in which an ordinary mixed diet of meat and vegetables, with meat rather restricted, is all that is required; (3) dropsical nephritis, where a strict chlorid-free diet should be chosen; (4) chronic hypertensive, or uremia-provoking nephritis, in which the diet depends to a certain extent on the stage at which the disease is treated. "If, in the early stage of the disease, a prophylactic diet containing little salt and very little nitrogen is regarded as unnecessarily severe, the same cannot be said of the later stages, when it may even be necessary to order a complete fast or at best a strictly fruitarian *régime* for several days in succession." (5) Lithiasis, in which the diet is the same as that for gout and is, therefore, poor in nitrogen.

The technic of the dietaries is given in detail. Special emphasis is laid on the water intake, concerning which the author says decision is often difficult. In mild cases of edema due to chlorid retention, the fluid intake should be reduced to 1,000 cc. or 500 cc. in twenty-four hours. In severe cases with cardiac dilatation, fluid should be entirely suspended for one or two days. At a later stage, the maximum amount allowed should not exceed 1,000 to 1,250 cc. In uremia-provoking nephritis 1½ to 2 liters of water are necessary; in lithiasis, 2 to 2½ liters.

Pritchard writes on the connection between food and disease in infants, in which the main argument seems to be, "the great majority of the diet diseases of infants are due to excess in the total quantity of food, irrespective of the precise qualitative make-up. The injuries caused are in the main due either to intestinal toxemias or to incomplete combustion by the processes of internal metabolism. The organism bristles with protective mechanism to prevent these serious results of over-feeding, but the calling into play of even the least harmful of them produces pathological results."

Diet in tuberculosis and pulmonary disease by Marcus Paterson reviews this author's well known ideas. Overfeeding should never be practiced in tuberculosis, and the diet must take into consideration the patient's specific resistance and dyspepsia due to any other cause.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

MODERN HEALTH MACHINERY IN DIAGRAMS

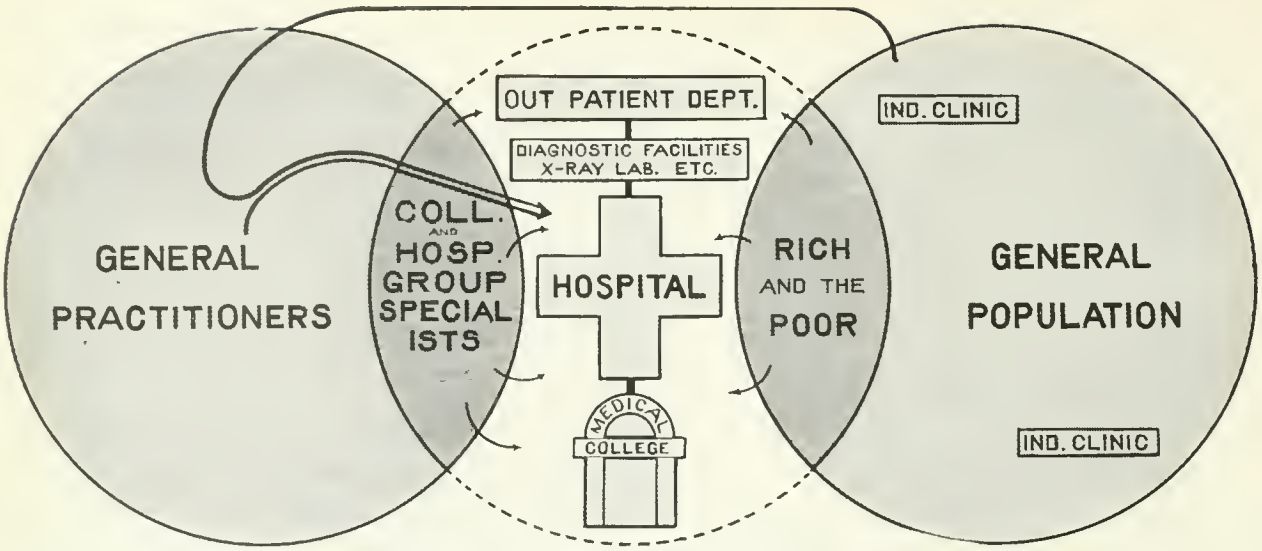
A CONTINUED effort has been made in these columns to impress the profession with the necessity of a realization that the practice of medicine is threatened with organic changes; that these changes will be planned by those who are less qualified than ourselves and will be thrust upon us from without, unless we immediately and vigorously attack our own shortcomings. With the hope of stimulating discussion in this regard several suggestive diagrams are herewith presented. In the first diagram an attempt has been made to portray the outstanding features of medical practice as they obtain today. It purposes to show how inaccessible are the best diagnostic facilities and treatment that the profession affords to the average practitioner and to the average patient. These facilities, provided at public expense, should not be accessible only to the rich and the poor. Furthermore, the Chinese wall between the leading physicians, the hospital groups and teachers, and the profession at large, must be removed. Efforts must be made to democratize knowledge to promote better medical service for the great producing masses of the people. The present unwieldy scheme makes higher standards and adequate medical service difficult.

The keynote of the second diagram is the group diagnostic clinic, just in the infancy of its development in this country. A system of early diagnosis, prevention, and cure is the only means at hand that may make unnecessary that colossal state-wide structure, social insurance, intended to equalize and distribute the cost of burdensome illness. The proposed reorganization of medicine, herewith diagrammatically represented, is not suggested as an alternative for social medicine or compulsory sickness insurance. At all events, some rearrangement of our methods appears fundamental to the economic application of the science of medicine. It does seem certain that no social system of medicine should be considered legislatively until we have cleared away the present *debris* of the intensively individualistic method of practice. Failure so to anticipate any proposed legislation will but invite medical chaos, and deny to the great producing groups the best that the profession has to offer. Here, even more than in England, the panel system will attract the less desirable members of the profession. We must take care lest in saddling the load of illness upon the state, we do not at the same time still the public conscience as to the crime of permitting preventable disease to go on unchallenged, and thereby weaken the present interest in and expenditure for preventive public health activities.

The proponents of social insurance imagine they have hitched their wagon to a star, whereas we mortals know that they have simply got the cart before the horse. Let us be forewarned, moreover, that in the present state of public mind many people are engaged in legislative star-gazing, and it behooves the profession to keep its feet as well as its eyes on the ground.

The following considerations further amplify the thought underlying the diagrams and charts, and should be taken into account as the same are studied:

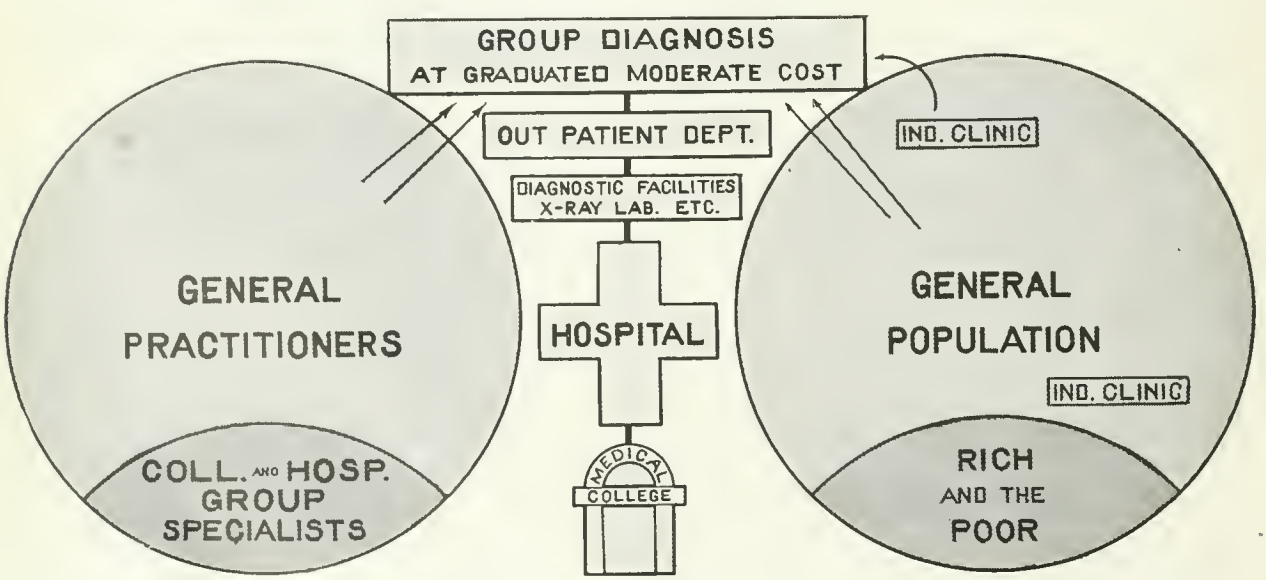
1. The field of medical endeavor, preventive and curative, if fully developed, is larger than could to-day be handled by all of the physicians and present hospitals and clinics.
2. The development of industrial medicine as a specialty has stressed the immediate and economic value of preventive health work to industry and labor. It is encouraging the extension of public health control.
3. The industrial physician is in turn teaching the earlier and more frequent use of the family physician and consultants, thereby improving the financial status of the profession. His reference of patients to specialists increases their practice.
4. High type of industrial practice teaches the worker to select for himself and his family a



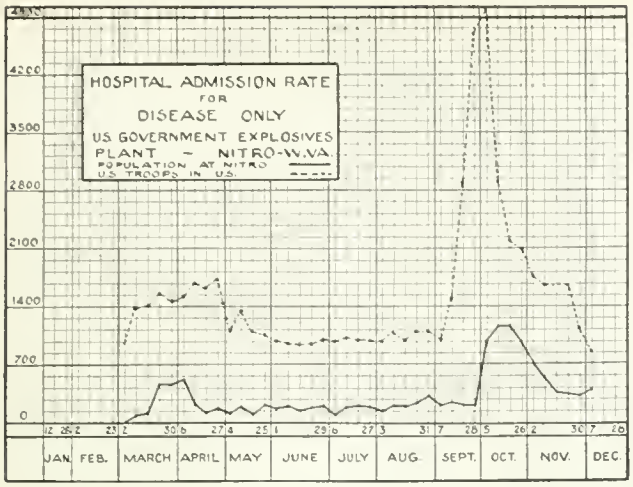
Outstanding features of medical practice as they obtain to-day are portrayed in this diagram. The most obvious is the inaccessibility of the best diagnostic facilities and treatment to the average practitioner and the average patient.

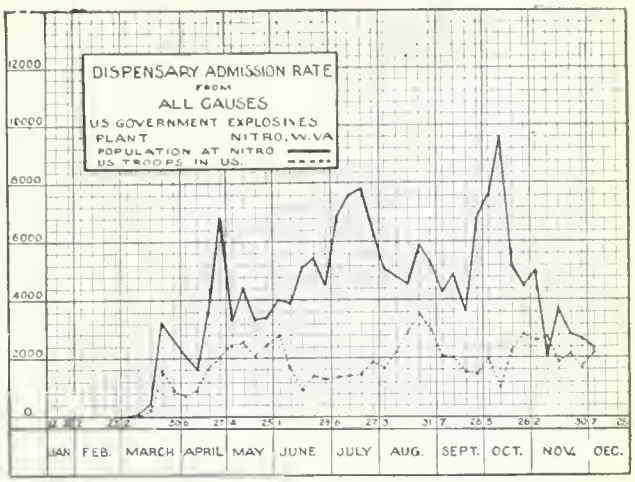
good medical practitioner rather than the average type. This selection should result in more useful service and fewer death certificates.

5. Higher standards of practice must prevail. To accomplish this the profession at large must be kept in closer touch with the teaching portion of the profession. Diagnostic service, group consultation and clinics, laboratory, and x-ray facilities must be made more accessible. This plan will perhaps reduce on the average the large incomes of the specialists, but will improve the financial status of the practitioner. The latter's energies will more and more be engaged in keeping people well.
6. There is considerable dissatisfaction in the laity with our conduct of the medical situation. A strong current for the socialization of medicine is under way. This can be resisted by the profession only through an intelligent, intensive study of the social and economic status of medicine which will result in constructive substitute measures and adjustments being offered to meet the situation. The day of extreme individualism in medicine is past. It remains for us to determine whether we are sufficiently statesmanlike to put our own house in order, and thereby avoid the deadening effect of such measures as social insurance so generally adopted abroad.
7. Increased production the world over is paramount. Most countries are bankrupt. New



The keynote of this diagram is the group diagnostic clinic, the only means at hand that may render unnecessary that statewide structure, social insurance. Rearrangement of medical methods along such lines as the diagram indicates is fundamental to the economic application of the science of medicine.





At left: Chart shows that the hospital admission rate in the army, where sick call is more or less perfunctory, is three times as great as the rate of the population at the government plant at Nitro, W. Va. At right: The dispensary admission rate of the army, as the chart shows, is but one-half the dispensary rate of the population.

energies must be released through improved industrial relations and through improved health of the worker, so that he may produce more and earn more. The physician holds the key to both these situations. Will he use his opportunities?

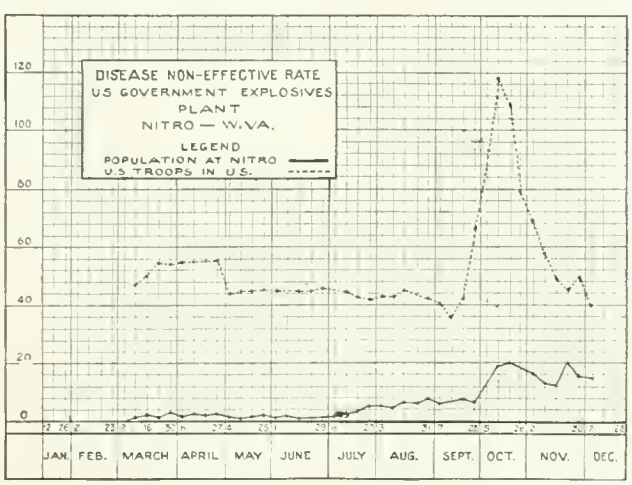
Increases Dispensary Admission Rate

We are indebted to Dr. J. A. Watkins, formerly with the United States Public Health Service and now with the Department of Industrial Medicine, University of Cincinnati, for the charts indicating in a most graphic way the effect of an intensive effort at preventive medicine on the disease non-effective rate. In charge at Nitro, W. Va., this industrial physician, stressing the importance of accessible clinics for early diagnosis and attention, to reduce hospitalization, brought remarkable results which strongly argue for the the development of group diagnostic clinics as indicated in the diagrams presented herewith. Doctor Watkins' charts are the more forceful in that his results are graphed alongside those of the army. It is a matter of general acceptance that sick call in the army is a more or less perfunctory act, and perforce followed by a higher hospital admission rate and hence a higher disease non-effective rate.

It would seem remarkable that the disease non-effective rate of the Army should be seven times that of the population at Nitro. This fact must be taken into account with the further facts that the dispensary rate of the Army was but one-half of the dispensary rate at Nitro and, further, that the hospital admission rate of the Army was, on the other hand three times as great.

The Army Dispensary Figures

Some objections may be raised to any such comparisons, but it is necessary to contrast these Nitro experiences with other large group data properly to evaluate them. Urban statistics are not only unavailable, but are not comparable in many respects. To a certain degree neither are Army statistics truly comparable; however, conditions existing in Army mobilization camps in the United States during this period of time more nearly approximated conditions as they existed at Nitro. Therefore, for the purpose of graphic representation, they serve our purpose. These charts and figures are offered for what they are worth. It does seem that they do bear out the position that the industrial physicians have taken, — that the place to do effective preventive work is at the industrial clinics, which are accessible at any moment of the day, and are teaching the worker to come to the individual physician for his most trivial sickness, and are thereby reducing the more serious illness and lessening the absence from work.



The disease non-effective rate of the army was seven times that of the population at Nitro, W. Va., a plea for industrial clinics.

THE APPLICATION OF WAR SURGERY TO INDUSTRIAL PRACTICE

By DRURY HINTON, M.D., Medical Supervisor, Harrison Works, E. I. du Pont de Nemours & Co., Philadelphia*

WAR is an industry and the injuries are industrial accidents occurring in the business of war. War differs from industry only in that the injuries are more numerous, and the destruction more extensive. In war the man power moves rapidly at times; hence the provision for those who are injured must in part be mobile. War injuries affect healthy young men, those who best react to trauma. This is not true of other industries, but compensation is provided by the circumstance that surgical help is immediately available, while in war injuries this is rarely the case.

The larger surgical lessons taught by the enormous clinical material incident to the recent boom in the industry of war bear upon: (1) The treatment of shock, (2) the prevention and treatment of tetanus, (3) the treatment of open fractures, (4) the treatment of infected joints, (5) the treatment of wounds, and (6) the treatment of chest wounds.

The Treatment of Shock

Practical experience and laboratory research in the zone of war activity have proved that in shock strychnin and camphorated oil have no value; indeed the reverse, and that rest, heat, relief of pain, by morphia if necessary, and an addition to the blood volume by transfusion give the best results. It has further been shown that dead tissue undergoes protein breakdown with the production of toxic substances which, when absorbed, may cause and aggravate shock.

Emphasis should be laid on the fact that in the presence of a severely crushed part, the best way to avoid shock is by the immediate excision of all dead tissue.

Doctor Cannon has shown in experiments that if an animal's limb is severely crushed, shock is produced. On the other hand, if the blood supply is first cut off by means of a tourniquet, shock does not occur, though it promptly appears when the tourniquet is removed. However, should the wound be thoroughly treated surgically and the tourniquet removed, shock does not develop. Therefore, in a wounded man, if a tourniquet is in place, it should not be removed until the dead tissue is excised, and it follows that a tourniquet until dead tissue may be removed is both rational, to arrest bleeding, and desirable to prevent absorption.

Treatment of established shock has been preferably to wrap the man in blankets in the folds of which are numerous hot water bottles. Heat supplied in this way is more effective than the electric light, inasmuch as evaporation is less. The patient is given enough morphia to stop pain, and one to two pints of saline, by enteroclysis or intravenous method, or, preferably, a transfusion of 800 cc. of whole blood. Thorough operation as soon as possible is indicated.

In an experience of fifty odd transfusions with the Kempton-Brown tubes for shock, hemorrhage, or both, it was found possible for one man to do the actual operation in ten to fifteen minutes on the ward. The experience of the American Expeditionary Forces has been that the citrate method is simpler, and almost as efficacious, requiring less skill in operation and less time to administer the blood. However, if available, whole blood is always preferable to the citrated blood. The incision for a transfusion need never be longer than three-eighths of an inch.

The Prevention and Treatment of Tetanus

The experience of war surgery has shown that the prevention of tetanus is a comparatively simple matter. Furthermore, it has proved that the immunity conferred by the tetanus antitoxin is of short duration. It has been found by the accumulated experience of many medical men, that the best way to administer the antitoxin for the prophylactic effect is to give three doses at week intervals, a primary dose of 1,500 units followed by two other doses of 500 to 750 units. In industrial practice tetanus may occur from puncture wounds by such instruments as rusty nails. There are industries however, *e.g.*, the steel industry, in which tetanus rarely occurs.

After tetanus has developed, it has been shown that the introduction of the tetanus antitoxin in enormous doses, preferably by intravenous and intramuscular injections, has given the best results. Therapeutically 300,000 units is a small dose. The British experience of good results from the intrathecal injections has not been duplicated by experiments in this country.

*Read before the Ninth Conference of Industrial Physicians and Surgeons with the Department of Labor and Industry, Harrisburg, Pa., September 22, 1919, in cooperation with the annual session of the Medical Society of the State of Pennsylvania.

The Treatment of Open Fractures

The best treatment of open war fractures has been: the early incision of the wound, not manipulating the bone until the wound surfaces have been thoroughly cleaned up; then the treatment of the bone fragments by the Hites-Boyer modification of the Leriche technic; in other words, the removal only of those fragments of bone which are not attached to periosteum, and of those which interfere with drainage. The fifty-one fractures closed by myself were treated however by the Leriche technic, which is apparently the better method where early closure is desired. Cautious closure without tension or dead space, and with due attention to drainage where indicated, is advised. It is best to close without drainage where possible. In those wounds in which there is a fracture but in which one is unable to close directly, it is a good procedure to make two lateral incisions, thus relieving the tension on the skin sufficiently to permit closure over the bone. In this way two wounds of the soft parts are left, but the danger of an osteomyelitis is materially reduced.

Proper splinting of the fractures deserves consideration. The most important fracture is the femur. The Thomas splint serves here admirably. Likewise the Thomas arm and the Jones arm splints are most useful in fractures of the humerus. Traction is applied by tapes or gauze fastened to the part by Sinclair's paste. For fractures of the lower third of the femur and when it is desired to flex the knee joint, the caliper extension modified by Doctor Furness is both simple and practical.

The Treatment of Infected Joints

Another benefit accruing to industrial practice from war experience is the dictum of Wilms and Gosset on the treatment of wounds involving and in the vicinity of joints, particularly those which are infected.

From the very beginning, full motion of the injured joint by the patient seems to have given excellent results, though contrary to all previous surgical belief. This has been successful even in panarthritis of the knee; one may see the patient moving the joint, and the pus squirting out at each flexion and extension.

The Treatment of Wounds

War surgery has demonstrated what has been long known, *viz.*, that the dead never come to life, whether it be mass death or molecular death; that molecular life needs a free supply of blood flowing through its supplying vessels.

The lessons of largest application and hence of greatest importance bear upon the treatment of wounds. These are: (1) the fact that blood flowing freely through its vessels is clinically the most effective antiseptic known to science; (2) that dead tissue is always a fine culture medium, and cannot be sterilized by any available antiseptic. From which it follows, and has been clinically proved in hundreds of thousands of cases, that dead tissue in mass is and invariably becomes infected and healthy tissues cannot be approximated and heal while dead material remains.

The clinical application of these lessons is that all dead materials must be removed by clean dissection and the sooner done, the greater chance of good results ensuing.

After the removal of dead tissues, the living must be approximated without dead spaces, and without tension to cut off the blood supply. Should dead space be left, it is filled with blood and serum, a dead non-vascularized tissue, offering favorable conditions for infection, which in vascularized tissues would be overcome by blood resistance.

If, after the removal of dead tissue, the vascularized surfaces can not be approximated at once without suturing with such tension that blood supply is cut off, war surgery has taught several methods of dealing with the problem efficaciously. These methods briefly are:

(1) *Partial Closure.*—This method consists of the approximation of as much of the wound surface as will come together without tension. After five days it will be found possible to close more or all of the remaining gap.

(2) *Flaps.*—The use of flaps is adopted for large areas, particularly if they be circular or oval.

(3) *Relaxation incisions.*—This procedure is adapted in particular to closure of compound fractures.

From a personal experience of 270 wounds sutured between the dates of August 7 and October 27, 1918, with an average delay of thirty hours after receiving the wound before reaching the base, good results were obtained: 228, 84.43 per cent, were successful; 10, 11.87 per cent, were failures; 32, 4.7 per cent, were partially successful, inasmuch as more than half of the wound healed without infection. Of the 62 wounds involving only skin and subcutaneous tissues, 54, or 87.1 per cent, were successful, and 1, or 1.6 per cent, were failures. Of the 157 wounds involving in addition the soft parts, 134, or 85.4 per cent, were successful and 6, or 3.8 per cent, were failures. Of the 51 wounds involving in addition a fracture, 39, or 76.5 per cent, were successful and 3, or 5.9 per cent, were failures.

On the other hand, of the ten failures three involved bone, six soft parts and one skin, there being one failure to every 62 wounds of the skin, to every 26 wounds of soft parts, and to every 17 wounds of bone.

Of the 112 cases treated by excision and suture 98, 87.5 per cent, were successful; 4, 3.6 per cent, were failures. Of 124 cases handled by delayed primary suture 106, 85.5 per cent, were successful; 3, 2.4 per cent, were failures. Secondary suture was used in 34 cases of which 24, 70.6 per cent, were successful, and 3, 8.8 per cent, were failures.

From this it can be seen that the sooner the closure operation the more successful the result.

The last 135 cases were cultured on the operating table; 34, 25 per cent, were negative and 101, 75 per cent, were positive.

Wounds clinically but not bacteriologically clean did well after suture. Had Carrel's dictum been strictly followed, less than 50 per cent of these cases would have been suturable. This is a lesson that can be applied to industrial surgery.

Most of these wounds were excised under novocain, occasionally supplemented by nitrous oxid plus oxygen, and so could be readily done in a works dispensary.

The time interval between wound and suture in an industrial plant should be almost negligible. If good results are obtainable when thirty hours have elapsed, they should be better when the interval is cut down, *i.e.*, when care is given during the first ten hours, or the period of contamination. After this time, we get the period of infection proper.

All wounds, whether they occur in war or in industry, are potentially infected at the time of the trauma. In war the infecting agency is the missile, clothing, and the dirt on the clothing. In industry, it is the accumulated grease and dirt in or with which the man is working.

Iodin has been used abundantly both at the front and in industry. Its efficacy as an antiseptic hinges on its intelligent use. It cannot sterilize dead tissue, but it kills the bacteria on the surface. After the removal of the dead tissue it is more useful.

First aid packets as a factor in decreasing virulence of infection act mainly by excluding subsequent infection, rather than by any specific action on the infecting agency at the time employed.

Dichloramin-T did best on flat surfaces, for example on amputation stumps. However, methyl alcohol dehydrated and clinically sterilized a wound quicker than any other antiseptic dealt with. Infected wounds cleared up most rapidly under hot soaks, or hot dressings, changed repeatedly.

INDICES FOR OR AGAINST IMMEDIATE OR DELAYED SUTURE

Immediate Suture	*Delayed Suture.*
1. Short elapsed time.	1. Long elapsed time.
2. Incised wounds.	2. Crushed wounds.
3. Good vascularity.	3. Bone damage.
	4. Slight inflammatory rex.
	5. Shock.

Treatment of Chest Wounds

The present war has shown that operative interference with the thoracic cavity is much simpler than previously supposed. No longer does one need the positive and negative pressure cabinets. Collapse of one lung is not as dangerous as has been taught. When chest wounds are met with they are handled in much the same way as we treat other wounds, meaning by this, proper incision and adequate drainage are instituted where indicated. The pleural cavity possesses a resistance to infection in much the same manner as does the peritoneal cavity. Sucking chest wounds should be closed immediately, either by suture, or tight pad until the patient can be sent to a hospital.

Conclusions

(1) Where death, molecular or mass, is present, infection is present also, and healing cannot occur until the dead tissue has been removed and well vascularized surfaces approximated without tension or dead space.

(2) The great problem of all wounds is infection.

(3) No antiseptic will sterilize so surely as the knife will cure.

(4) The time element is all important. Operate early and thoroughly to get the best results.

(5) Closure of a wound is preferably done by clinical judgment alone.

(6) Given a clean-cut operation, no antiseptic is necessary.

(7) Use of local anesthesia is applicable to industry. Novocain is the anesthesia of preference.

(8) Immediate surgery is the best preventive of shock.

(9) Proper splinting of fractures and traction can be done in a works dispensary.

(10) Early functioning of joints whether in joint injury or fracture should be started immediately; this should be active rather than passive.

(11) The fear of operative interference in chest injuries has been largely dispelled.

If you want to be miserable, think about yourself, about what you want, what you like, what respect people ought to pay you, and what people think of you.—Charles Kingsley.

THE PHYSICIAN AND SURGEON IN THE INDUSTRIAL CRISIS

OTTO P. GEIER, M.D., CINCINNATI, OHIO*

In an ever-broadening field, medical and surgical service in industry conserves the body and mind of the worker, humanizes his place of work and changes his attitude toward his job and the plant.

The next advance toward industrial peace must be the recognition that team play,—cooperation,—between employer and employee will serve the interests of both.

The service of the physician as an intermediary between employer and employee is to translate preventable accident or sickness into terms of economic loss to both, and to persuade them that the interests of both lie in mutualism, the sharing of both benefits and obligations.

IN the great chaos of world thought today, two outstanding problems present themselves for solution: First, how may international peace be brought about? Second, how may industrial or national peace be brought about? I hold that these two questions are inseparable. Permanent international peace will never exist until there be peace and unity among the people that go to make up each nation. The master minds of the world are at work on the first problem. The second problem, touching upon industrial peace, the success, health, unity, and contentment of the people of the nation, is the one that now concerns us. It is individual; it is directly and universally personal. No one of us can escape the responsibility of finding answer to the question that bears on the success, health, and peace that shall come to each individual, the sum total of which is finally forged into a national life. How this may be brought about; how these individuals may be drawn nearer to an established order of peace and harmony; how they may be influenced toward maximum production for their own and for the community welfare; how they may be brought to their best citizenship, actively in support of their own government; and, finally, how that government may come to be but the composite expression of the best desires and ambitions of men, is the special challenge that comes to the medical profession.

An Era of Conflict

It has been indelibly impressed on us these past few years that if the majority of the persons that make up a nation are badly dealt with; if they believe injustice prevails, if they feel that their living and working conditions are unfair, then a state of unrest and publicly expressed dissatisfaction results; production is interfered with; suffering and want ensue. Government then becomes unstable, and crime of every known variety becomes rampant. These things are destructive to citizenship—they are a blight on national life. Our subject, the physician and surgeon in the industrial era, is most timely. This is not only the industrial era, but also the era of greatest industrial strife. Public disorder and strife originate almost wholly in the clash of opinion between organized money and organized labor. Strikes and lock-outs with their attendant turmoil are but outward signs of a constant warfare that is going on between these groups. Thus we are uncomfortably reminded daily that ours is the industrial era; that the individualistic viewpoint no longer holds; that we must adjust our work and our thinking to large groups and great units of society; that we must think in terms of the mass rather than of the individual; that this is the day of group action; that this is the day for mass treatment.

The Peril of Stagnation

Recall, if you will, the national peril of business stagnation and starvation that England has just faced. Recall also the similar situation in our own country three years ago, when the railroad brotherhoods forced the Nation to its knees in the passage of the Adamson Law. Its recent arrogant progeny is the Plumb Bill. We have but just passed the crisis of the steel strike, only to be threatened by a coal famine with its almost limitless possibilities for nation-wide disaster. Here the ultimatum of organized labor is for a six-hour day, a five-day week, and 60 per cent increased pay. This is but another example of the vicious, ever widening circle of higher costs with lowered production,—yes, actual shortage of an industrial and domestic necessity.

* Read before the Clinical Congress of the American College of Surgeons, Ninth Annual Meeting, New York, October 20-24, 1919.

This type of demand by labor, coupled with successful propaganda by the I. W. W., the Bolsheviki, and the radical socialists, arrests the attention of all serious thinking men. Russia exemplified what happens to industry and production when rampant radicalism overwhelms a country. Industrial stagnation, insufficient production, hunger, mean a revolution. All men and groups of men of any moral or mental status or leadership, must definitely assign themselves to the task of stilling the present unrest. Selfish interest and self welfare demand it. The wave of temporary patriotism is over. Patient understanding and daily patriotism must prevail for the future years. No class is more challenged by these facts than is the outstanding group of physicians and surgeons.

The Psychic Wave and the Physician

What part is our profession playing in this post-war psychology, this industrial and social crisis? Are we making our contribution to the study of the problems of industry and labor? Have we adjusted the science of medicine to the needs of these two groups, or have we practised our profession with individuals just as was appropriate one hundred years ago? Have we not failed to develop a consciousness of group problems?

Bear with me in asking these personal questions. Is it not paradoxical that the physician, who to his patient appears as the most socially minded individual, should prove so unsocial and so inactive in his public thinking? Is it not strange that we who have the closest view of the intimate living and thinking of the people, should play so small a part in the disposition of their individual or group lives? Dare we any longer stand aloof and fail to make ourselves felt in the great social and economic changes that are taking place? Is it not equally strange that we should retain such a narrow perspective of the capacity of the profession to assist in these national problems? Health and sanity; these are basic factors in all social consideration. Are we doing all we can to bring them about? This would seem to be our especial function in society, and yet the most far reaching social measures which have to do with care and cure of disease and accident have been, and are being framed into legislation without taking the medical profession into account.

As an illustration, were our surgeons carefully consulted when Workmen's Compensation Acts, for the care of industrial accidents, were established? Are we satisfied with the application of this Law? Is it not a fact that, generally speaking, medical men, not qualified surgeons, are tinkering with the industrially injured? For the worker, this means prolongation of the case, greater loss of wage, unnecessary invalidity, with practically no scientific rehabilitation. For the employer, this means the idle machine, lowered production with higher cost; for society, it inevitably means definitely lowered standards of living and higher costs of living.

Physicians Should Claim Initiative

On the other hand, was the profession entitled to such consideration? Is it not a fact that for years we blindly went on repairing the hundreds of thousands annually injured and maimed, without public protest and without suggesting an improved program? It occurred to labor to seek compensation for time lost from accidents and payment by the state of the surgeons' fees. In the very nature of the case, labor could have no knowledge as to how to obtain the best surgical results for the injured, yet they dictated the law. Moreover, it remained for industry, not the medical profession, to set under way that wonderful "safety first" movement which has reduced death and accidents by approximately 50 per cent. Is the obligation not upon us now to propose the type of surgical organization under workmen's compensation acts, that will place all of the surgery rendered the injured workmen under the supervision of the best trained men in the profession, who, with a corps of assistants, and with the states divided into districts for such supervision, will see to it that justice is done both the injured worker and the profession?

Science in Sequestered Places

Are we not assuming the same negative attitude toward the movement for the better organized application of group curative medicine? Are not the physicians being practically ignored by the framers of compulsory sickness insurance, another group program? And yet we shall all admit that the future of the scientific teaching of medicine as well as its economic practice or application will be absolutely determined by the enactment of such a law. Unless the profession comes out of its social, or rather unsocial torpor, we may be sure that such legislation will be made to fit the whims of the perniciously active reformer, whether or not it pleases us or benefits labor or capital. Here again industry has been permitted unaided to visualize, ahead of the profession, the necessity of a constructive, preventive health program as an integral part of any intelligent legislation for health insurance. Does this recital of our social inactivities possibly suggest why we

have been so unsuccessful in our demands for a Federal department of health?

How can we understand and contribute to economic and social legislation unless we get a near view of the problems of labor and industry? Can we do this best merely by prolonging our scientific discussions in sequestered places or by also entering into the life and understanding of industry, learning there to apply our science intensively for the early recognition of disease and its prompt cure? It is here through supervision of the group that education of the adult for the prevention of disease and accident may be best applied. Energy applied to the group always means a maximum result with a minimum effort. On the other hand, can we hope to mould the attitude of organized labor toward health programs unless we offer a solution to the back breaking burden that preventable disease and suffering are causing the worker? Are we strong enough to overcome the objection of labor organizations to physical examination and prove that medical supervision of the worker is a national economic asset?

Better Basis of Thought

We must recognize that almost all old standards of thinking are in the discard. We are passing through a period of unstable thought. The pendulum has swung far and wide. The autocratic employer of yesterday is more than matched by the autocratic employee of today. The medical profession, along with a great mass of people, is in the arc of the swing, and must needs be on its guard.

If the world is to progress, the medical profession must render its best service and thereby prove indispensable to the main groups of society. Are we as a class perhaps the very latent force that if properly applied, will enable better relations between labor and capital, and establish a new confidence between these warring factions, a better understanding on the part of each of the difficulties and purposes of the other? We can help close the gap, to narrow the gulf, by humanizing industry. This approachment will come not by the fact that the physicians will act as mediators in any active struggle, but by daily furnishing human contacts on which better understanding and greater tolerance are created. In actual industrial practice the physician acts as the liaison force between employer and employee.

The Physician in Public Discussions

If such premise be sound, if any such hope of new human service exist, it behooves us as a profession to take inventory and better fit ourselves for this national reconstruction. We have still to demonstrate our worth. Our usefulness in public discussion of serious labor problems is not noteworthy.

Did it strike any of you as curious that the President failed to include a member of our profession in his national industrial conference at Washington, which began October 6?

Organized labor was given 17 representatives, four of whom were selected by the railroad brotherhoods; the United States Chamber of Commerce and the National Industrial Conference Board were each given 5 representatives; while the farmers' organization and the bankers' association are allowed 3 and 2 members, respectively. This would appear to indicate that the organized portions of society had their interests fairly well protected in this Conference. Can we say as much for the public, which all too frequently finds itself squeezed by the pressure which any two contending forces happen to exert on each other?

Science Must Serve the People

It is interesting, therefore, to note which of the fifty-seven varieties of statesmen appointed to the National Industrial Conference, are represented in the twenty-five individuals chosen to appear in behalf of the public. Unofficial record and "Who's Who in America" reveal the fact that the public was here represented by one broker; two bankers; two socialists,—one a writer and the other was once an aspirant for public office in New York; one president of a farm bureau federation; a cotton manufacturer; a clothing manufacturer; three directors of large corporations; one attorney for railroads; one paper bag manufacturer; one wagon manufacturer; one editor of a farm paper; one designated as a lawyer and politician; another known as "potato king"; one indicated as oil operator and lobbyist; one woman publicist; two women social workers; along with John D. Rockefeller, Jr., Elbert H. Gary, of the Steel Corporation, and Dr. Charles H. Eliot, president emeritus of Harvard College. Please note that the one hundred and fifty odd thousand of physicians in the country who have the obligation of caring for the nation's health were not represented in this Conference.

The one issue that is not controversial in this conference is that of decent living and working conditions. Within this issue are bound up problems of shop sanitation, the question of working conditions, prevention of occupational disease and accidents, and medical supervision with physical examination, to say nothing of the living conditions which involve housing and community health programs. These are factors in the in-

dustrial relations conference to which the physician with his scientific training and social viewpoint might have given invaluable suggestions; and yet we were, of all the professions, distinctly counted out. These are the things that make for the success, health, unity, and contentment of the people and are vital to national and international peace.

Waste in Delayed Service

If production is the keynote of a world reconstruction, and if health and sanity be so large a factor in production, would we not better move the physician out of his private office and into industry? Here he will soon become less an individualist. He need not be less scientific, but certainly he will be more usefully scientific as he touches elbows with those who rarely see or know the best that is in medicine or surgery. He will be applying to the great mass of workers, —the backbone of the nation,—that great storehouse of scientific knowledge and research which today is finding application in only a fractional part of the population.

It has become axiomatic that only the rich and the very poor get the best that we have to give as a profession. This fact becomes startling when viewed from the industrial clinic. The clinics of the hospitals or medical colleges meet only a fraction of the problem. The work there is with those who have fallen below the poverty line in whom it is too late to do preventive social work, and often too late to do preventive medical or surgical work. What a wondrous waste of energy! For only about 15 per cent of your clinical cases ever return for further observation. The clinic within industry prevents the unfortunate but good American workman from reaching the poverty line; it keeps him out of the charity class.

The Manifold Problems of Industry

Within the past decade there has developed, as a result of a strong demand on the part of industry, a new specialty to which hundreds of our profession are now devoting themselves. The industrial physician and surgeon are desperately attempting to cope with the manifold economic and social problems that are being brought to his attention. He is making himself familiar with the health problems of industrial institutions and those of the community. He is trying to make himself the master of the medical and surgical problems of industry, which are quite distinctive from those of the general practitioner and surgeon. He must have knowledge of the sanitary standards of plants, of occupational diseases, the subject of fatigue, the principles of safety work. He must know how to approach the subject of the medical supervision of the employees with special emphasis on physical examination, the proper placement of the employee, on dental hygiene, and nursing service. He must have a real interest in the broad question of personal relations in industry, must understand employment methods, with the proper recording of absence, lateness, illness and injury, labor turnover, and their bearing upon production. He must know the problem of the health of the employee in relation to the establishment funds, or mutual aid associations as well as the other factors of industrial health, such as recreation, food, cafeterias, rest periods, and so on.

The subject of lost time from work on account of illness, injury, and other causes is being continually related to the man's productivity and earning capacity, and in this way the physician's knowledge of medicine and surgery becomes a factor in economic life. It is the business of the industrial physician and surgeon to discover the existence of unhealthy working and factory conditions,—the matters of inadequate ventilation, lighting, drinking water, toilet and locker facilities.

These things, along with the occurrence of dust, fumes, gases, poisons, over-crowding, unnecessary noises, excessive variations in temperature and humidity, some of which produce an impaired vitality and low output, are his daily concern. The subject of fatigue, along with monotony, speed, and over-time, all become the problems of the industrial physician, to be weighed in as factors in efficiency and low earning capacity. Who can say how far fatigue brings on soreness of mind, and again how far soreness of mind predisposes to bodily fatigue? To what degree is that soreness of mind expressed in unrest?

The Physician a Social Engineer

When this type of work is well done, the physician becomes a social and medical engineer. He makes available to the mass of working men the best surgical and medical skill; he intensively educates the worker in the dollars and cents value of good health and personal hygiene; finally, and perhaps most important, he gives the employer the most accurate obtainable knowledge of the social, economic, and health conditions of the worker. He affords to the employing class interest in and a greater appreciation of the value of community health, thus making for the extension of public health control.

Out of this great human laboratory comes the conviction that the medical profession must

square itself with the conditions that obtain in this industrial era. This experience spells a need for group diagnostic clinics, where the average worker may pay a reasonable charge for the best diagnosis. The industrial clinic, acting as a diagnostic clearing station, is continually sending to the physician and surgeon on the outside cases requiring operative and medical procedure. Too frequently these patients are being charged out of proportion to their capacity to pay.

It may amaze you to know that the average worker receives his first complete physical examination in the industrial clinic. He is too often the victim of blind, gunshot prescriptions. The industrial clinic is teaching him to seek a better type of physician for himself and his family, and in that sense the industrial physician is tending to raise the standard of private practice on the outside.

In attempting to secure this better medical and surgical attention, the inadequacy of hospital and clinical facilities to care for the man who desires no charity, but who deserves the profession's best service at his price, becomes apparent. Whether the workman can receive his just dues in this regard without the intervention of some system of social insurance, remains for our profession, in conference with political and social economists, to determine.

Creates a Demand for Health

The industrial physician is doing much to mould opinion in behalf of preventive medicine. He is intensively educating the worker to care for his health. Our mortality rates can be further lowered only by such type of work, for the public seems to have reached a saturation point in regard to the educational appeals sent through the press by health departments. Industry can make use of the economic pressure to secure attendance to health matters.

The industrial physician recognizes not only the particular symptom of the patient in his clinic, but he visualizes through him the shop, the bench, the particular occupation that is affecting him; the dirt, the danger, the monotony, the home environment of the man before him. His preachments for healthful living are readily translated into the fact that each day of illness means a cramped budget at home; that prolonged absence on account of preventable accident is, through lowered production, adding to the cost of living.

It must be apparent that service of this type is more than mere medical or surgical service; that it is intensely conservative of the body and mind of the worker; that it humanizes his place of work; that it must change his attitude toward his job and officials in the plant; that it paves the way for clearer thinking and greater self-expression; that it substitutes a personality for the mere dull cog in the machine; that it calls out character both in the employer and the employee; that we thus secure an improved mass morality in both groups, and hasten the day of the true spirit of justice and good will in industry, the day of a real democracy between men.

These are some of the problems that the physician and surgeon of the industrial era must meet. These are questions which particularly challenge the attention of medical associations which have within their membership men with vision, who see things in a big way, who have shown an ability to do, who have developed a capacity for leadership.

Organizations are at hand to carry out any plan to reach any goal they may set for themselves. It is for them to evaluate this new specialty, to institute appropriate courses in medical colleges, to further its wider extension in industry. It is to be remembered that unless the task outlined for the industrial physician is accepted, there is no one else who can undertake the task and meet the situation.

The Dividing of the Way

It is for the medical profession at large to determine what place it will hold: whether in the swift current of thought, or in the quiet eddies; whether to stay on the edge of life, or close up to the great melting pot of human experience; whether to remain as spectators, or join in the struggle of progress; whether to rest in billet, or press on to the firing line, where men are fighting for life's goal.

The responsibility of leading the profession at large can well be left with this Association. I refuse to believe that you will not use your tremendous influence in this industrial crisis to set the people thinking sanely; that you will not assist in placing the medical profession back among the people,—the doers and the hewers; to reproduce the original place of the physician in society, that of priest, confessor, teacher, and healer; that you will not help place our medical, surgical, and philosophical service right out among the people; place it at the ignition point of life, where it can be consumed and help fashion into thought and being a national life commensurate with the standards of those who set up our great republic. The obligation is yours; the service asked, ennobling; the opportunity for enlarging life, immeasurable.

EYE INJURIES

By FRANK C. TREBILCOCK, M.D., Toronto, Canada*

EVERY man enjoys the opportunity of speaking to others upon his hobby, and I am no exception to the rule. I take it as an honor that I am allowed that privilege to-night, and herein desire to express to you my appreciation. Quite justly you have linked with that honor the responsibility of doing what has proved a rather difficult task, namely, of making a complicated and technical subject so simple and ordinary that I hope those of you, expert along other technical lines, may enjoy the paper, while my own *confrères* in the work may not weary.

Certainly phases of this wide subject were dealth with in a masterly manner at a previous convention by the president, Mr. George A. Kingston, but I hope to open others, so that, while perhaps reviewing some things of which he spoke, and adding others, your interest will be kept alive in this difficult group of cases.

Typical Cases Explained

I do not intend to enter into an abstruse discussion of any subdivision of this great subject, but to draw for you a picture or two of discrete cases, with explanatory remarks as we progress.

This claimant is a man of 54 years; comes from the country; he was injured by a flying spicule of slag, which pierced his right eyeball. He is accompanied by his wife, who generally answers for him, and volunteers the information that she came with him because he is unaccustomed to the city and might get lost. He holds his head down and cringes under the light; the attempt to get him into position for examination near a tungsten lamp causes most marked screwing up of the eyelids (blepharospasm). While writing some preliminary notes, we notice, by taking hidden glances at him, that the eyes are open and the spasm gone. The general behavior of the man, the volunteered and obvious support of the wife, suggest an exaggerated attempt to impress us with the serious results of the accident; perhaps he is badly injured; perhaps simply neurotic; perhaps malingering. Let us see.

The right eyeball has been injured; there is a scar in the scleral coat, extending downward from the corneal margin in a vertical direction for about three-sixteenths of an inch. It is dark colored and marks a perforation of the globe by a sharp foreign body,—in this case a piece of slag (glass). Above the wound area there is a small diffuse, grayish scarring, but it is limited in area, and does not extend into the center of the cornea, so that the part over the pupil is preserved in its perfect transparency.

The wound area does not bulge, is soundly healed, and there is no evidence of corneal or conjunctival irritation. So far as the outer wall of this eye is concerned excellent recovery has followed the wounding.

Let us return now to his lid spasm in the presence of light and the hanging of the head. Now, photophobia or horror of light is nearly always dependent upon superficial lesions; remember how the children suffered when their eyes were sore in measles; or try to forget your own distress when you had that cinder in your eye; and these are manifestly surface irritations. So that, with the mucous membrane of this eye so free from evidence of irritation, the healed wound, and the clear cornea, the man ought not to have photophobia and blepharospasm.

The Signs of Abnormality

But below this surface structure there is sign of abnormality. The pupil is not round, as it should be, but is elongated vertically until its lower edge is lost behind the corneal rim. This gives us the so-called keyhole pupil; the absence of the segment of the iris is named coloboma. Such shaped pupils are occasionally seen in congenital abnormalities, but we are justified in considering this one as a sequel to the accident.

There has been perforation of the external coat of the eyeball; a spicule of slag has made a vertical stab into the rim of the anterior chamber of the globe and, on its withdrawal, the squeeze of the muscles which move the eyeball in the socket has tended to empty the contents through this small opening. Some water first escaped; then, luckily, the iris below the pupil was forced into or against the inner aspect of the wound, and all leakage ceased. Healing took place without infection, but the slight inflammatory bands or adhesions held this part of the iris in its new position, and when final repair is complete it can not return to its normal place; the coloboma is permanent. The only point of danger is that this bit of iris may be forced into or through the wound as my handkerchief lies between my fingers, and

*Read before the Sixth Annual Meeting of the International Association of Industrial Accident Boards and Commissions, Toronto, September 23-26, 1919.

so interfere with the coaptation of the wound edges and prevent satisfactory healing.

In the case under discussion either that complication did not take place or the offending part was successfully removed by the attending surgeon, for here we have a perfect scar.

Looking now at this keyhole pupil under varying intensities of light we see that the free edge moves from center to periphery, and *vice versa*, except in that segment where it is glued to the undersurface of the wound area. This pupil is moveable, as it should be, except where mechanically tied and, as the color of the iris is exactly like the other one, we decide that there is no permanent damage done here for, unless complicated, we do not consider the coloboma a very serious matter.

A glance into the keyhole pupil shows it black as the other one, so that if there be no deeper injury, little harm has been done.

The examination of the deeper parts of this eyeball is now made in the dark room by reflected light. This is not easy to demonstrate to the unpractised man, so that you will have to accept our word for it that there is no lesion to be made out; that is to say, the crystalline lens is in its proper place immediately behind the iris and supporting it, and is perfectly transparent. Had it been scratched or pierced by the spicule of slag, it is probable that it would show a definite cloudiness, certainly at the point of injury, and likely throughout its entire substance; that is, we would have a cataract following the puncture,—the typical traumatic cataract.

In the case before us, either the glass needle did not penetrate deeply enough to touch the lens or it entered so far from the corneal margin as to be external to the rim of the lens, whose position is roughly indicated by the circumference of the cornea.

Searching carefully the posterior segment of the globe, that part behind the crystalline lens, we can find no sign of any lesion. All the structures therein contained, so sensitive to injury, so important in the process of proper and exact optic nerve stimulation, are normal in appearance.

We should now know this eyeball from the physical standpoint thoroughly; we have noted the cosmetic blemish, the abnormal pupil, but are sure that in the direct pathway of the light rays from the object reflecting them to the retina of the eye there is no obstruction visible to our normal sight. We must conclude that so far as this eyeball is concerned the claimant ought to see, and to see almost perfectly.

I have purposely explained the eye condition to you in detail before letting you know his complaint; it is that he can not see anything with his injured eye, and that his good one is getting weaker. He is emphatic that he can not count my fingers at one foot with his right eye. The vision of his left eye, the uninjured one, is admitted to be 6/24ths, but is improved to normal, 6/6ths, with a spherical lens of one unit.

The very exaggerated contortions when he first came near the light, the normal pathway for the light rays, with denial of sight, and the indefinable atmosphere about the man have aroused our suspicions of fraud from the beginning. It remains to prove the fraud and to make it clear to the man himself.

A Test of Vision

He sits opposite the ordinary testing card; with both eyes open he is told to read, and he reads easily lines one, two, and three. Into a pair of spectacle frames which he wears we put two convex lenses, so strong as to blur these lines and make them unreadable. He says he can not read the top letter now. Next, in front of these lenses we place other two, but not mates,—in front of the injured eye a concave one of the same units as the convex one already there,—so that this convex one is now neutralized, and for examination purposes he now wears over the injured eye what is equal to glass, or to no glass at all. Over the good eye we place another convex glass, so that the strength of the lens already there is added to and the blur increased for this eye,—the blur which he admitted a moment ago. These additions must be made quickly and simultaneously, and he must not be allowed to close either eye. You will understand that whatever he can read now he will see with the injured eye, although he will suppose that he is still using both together.

He is now asked to read; is asked without delay, for he must not have time to think; and our conduct and conversation must not suggest that we are trying to put him in a corner. Without a falter he reads the third line from the top of the card just as he did before, and it is obvious to us that he reads it with the eye which a few minutes ago he declared was so blind that he could not see his hand before his face. By covering this eye and giving him a new card, he will have to admit that his good eye can not read the top letter, and that he really was reading with the injured eye.

There is therefore no disability, for the right eye sees as well as the left one. This one fact is the end of our interest in the case.

Of course there are confirmatory tests which may be used, but in this case none was necessary,

and I will not weary you with details of them.

Before leaving this type of accident let me cite another case of almost identical wounding, with results more happy from the cosmetic standpoint, more unfortunate from the economic one. This man had the same sort of injury,—a stab by a bit of slag, sharp as a knife needle. The position of the external wound was just inside the corneal margin, instead of outside, and the penetration deep enough to puncture the iris, making a permanent eccentric pupil and piercing the lens. At first I was anxious lest a small particle might be still in the globe, but as the x-ray will not show glass, there was no way of making sure on this point. In an hour after the puncture took place there were such changes in the lens transparency that one could not distinctly see the details of the vitreous chamber; the traumatic cataract was already developing. The sight of this eye is permanently very defective.

These two cases taken together illustrate many points frequently seen in punctured wounding of the eyeball, which remains free from infection: the scleral pigmented wound, the coloboma of the iris, the perforation of the iris without iritis, the permanent eccentric pupil, the traumatic cataract following the prick of the lens. I am glad to say that the attempt at fraud is rare.

Traumatic Cataract

The brief review of this second case leads us naturally to a discussion of the subject of traumatic cataract. In the paper read before you two years ago by the President your attention was drawn to those lens changes of obscure origin which occasionally follow high-tension electric charges. The type of which I speak now is much easier to explain. This ordinary variety follows a break in the integrity of the lens capsule, that skin-like bag which incloses the proper substance of the lens in the same way that the chamois-skin pouch inclosed the chase gold watches of our fathers. So long as this capsule is intact the crystalline lens is protected from the clouding influence of the contact with the water humor just in front of it; but if a rent takes place in the capsule so that this aqueous humor can get through, then perfect transparency is lessened and cataractous change begins. I suppose that we would be justified in saying that the great majority of punctured eyeball wounds in the area covering the lens are followed by traumatic cataract, with defective vision, often complete loss.

From one standpoint this sequel to accident may be considered a fortunate one among the many which may occur, because the cataractous crystalline lens can be removed and, if there be no complications, either of the original wound or at the time of operation, satisfactory vision may be restored; however, in practice the problem is a difficult one. It is so easy to say to the patient, "Wait a while, until all signs of irritation are safely past; then we will extract the cataract, and it is a good gamble that a reasonable measure of sight may be regained."

Sequelae of Operations

We have instances where such a course was followed; traumatic cataracts were very successfully removed, and excellent sight regained in the injured eyes; but persistent double vision worried the men when both eyes were used together, and the surgeons would be as delighted to return to the men their cataracts as the men would be to get them. This is, happily, a rare sequel to operation, but must be always kept in mind and fully explained to the patient when he asks for operation. I shall not worry you with the elaborate explanation of this complication, but remember that a lens of approximately three-inch focus has been removed from the eyeball and, if anything like normal vision is to be achieved, a lens of equal strength or near it must be worn in a spectacle frame in front of the eye. This new arrangement works very well, indeed, in the vast majority of cases where the eyes can not be used together, as when the other one is defective; and it works well in many cases where the uninjured one is normal; but occasionally it will not work at all. It seems to me that when one eye is performing its function normally and the operated one has to be so artificially assisted, the miracle is that any of them work well.

I know that one seldom hears complaints after these operations for traumatic cataracts, but we must not forget that there are a very large number of these patients who, having deeper injuries, do not get good enough vision to cause the annoyance; and then there are exigencies at some operations which mar the outcome. I do not suggest that traumatic cataracts should not be removed when the vision of the uninjured eye is normal; I only maintain that it is a difficult problem to decide what will be best for the patient, especially when he does his work without much inconvenience, and the only indication for operation is either the cosmetic one or the widening of his visual field. I think that all the possibilities should be discussed with intelligent patients until we see that they fully understand, and that then they should be given the right and the duty of choice; and that in cases when the injured ones are unintelligent or illiterate it is better to leave well enough alone.

OCULAR WORK OF THE HOOD RUBBER COMPANY

HARRY A. WATTS, M.D., Assistant Ophthalmic Surgeon, Massachusetts Homeopathic Hospital; Oculist, Hood Rubber Company, Watertown, Mass.

EARLY in 1918 the large percentage of ocular defects occurring among applicants and employees made obvious the need of ocular service in connection with the health department of the Hood Rubber Company.

Upon examining, for example, fifty-five inspectors, it was found that eleven, or 20 per cent, could not see the work they were paid to to inspect. The development of this branch of service has been so important to this company that it seems worth while to call it to the attention of other industrial establishments as well as to oculists.

One of the most difficult problems at the outset was the best way of handling the mechanical and optical side of the service. The question of installing a complete grinding equipment and employing an optician was carefully considered but rejected, chiefly because of the additional cost. Instead, arrangements were made with a Boston manufacturing concern that sends to the factory a competent man who takes the prescriptions and measurements for the mountings, delivers the glasses, and makes adjustments. This firm gives the Hood Company a discount on all glasses so that they can be sold to the employees at a considerable reduction under prevailing prices. Collections are made by the Hood Company either in cash or by deductions from the pay envelope, sometimes in several installments.

The following table will show the highly cosmopolitan character of the employees and give some idea of the kind of people with whom we have to deal and the problems to be met:

On April first the 8,338 employes of the company were tabulated as to nationality as follows:

American	340	French	126
Italian	254	Swede	70
Irish	226	Scotch	58
Canadian	171	Hebrew	18
Armenian	161	Norwegian	17
Lithuanian	159	German	11
Greek	3,995	Turks	9
Polish	1,233	Danish	8
English	551	Austrian	7
Portugese	459	All others	40
Russian	425		

The age distribution was listed as follows:

14—15	126	41—44	484
16—17	481	45—48	385
18—20	957	49—52	263
21—24	1,594	53—56	200
25—28	1,226	57—60	117
29—32	945	61—64	56
33—36	824	65—68	41
37—40	624	69—72	15
Total	8,338		

Treatment Optional With Employees

The new eye service was advertised in the factory by posters and notices in the *Arrow*, the company magazine. Defectives discovered at the time of physical examination are referred to the clinic for treatment. It is purely optional on the part of the employees and does not include any members of their families. We started giving three mornings a week to the service, but the response to the privilege was so prompt that we began in July to devote every forenoon to the work and have continued on that basis since.

We started to follow the system used in the ophthalmic out-patient departments of the various Boston hospitals,—with patients thirty-five years or younger, to take and record the vision at the first visit and give a bottle of homatropin, with directions for use, and orders to report on another day with the eyes under its effects. With this system we soon found we had a long list of employees who had a bottle of our homatropin at seventy-nine cents per grain, and a dropper, who never came back. We found it necessary to avoid the use of drops whenever possible and it is used now only when it seems absolutely essential for a positive and reliable diagnosis.

Nature of Complaints

These patients come complaining of some type of asthenopia, and the relief of this or the improvement of their vision is all they wish; if this can be done without the use of drops every one concerned gains thereby. It does not seem possible to dispense with the use of a mydriatic entirely and maintain a high standard of work. In a few cases the ciliary muscle is so active that hyperopes make apparent myopes of themselves and refuse everything except minus lenses, which it would be grave error to give. Without the use of drops it requires unceasing vigilance to avoid this error; even then, it is apt to occur occasionally.

One extreme example of this type was that of a young woman thirty-five years of age who suffered from very severe headaches. With ordinary methods of refraction she absolutely refused every lens except a minus .75 and that with a result so unsatisfactory as to be clearly unreliable. With homatropin she accepted plus 1.50 sph. O. U. with a plus 50 cyl. which gave her immediate

relief. This case is an example of a type in which a mydriatic seems indispensable.

As a substitute for homatropin fogging systems have very warm advocates chiefly among those who, because of a total lack of any medical training, are forbidden by law to use drugs. We use it in cases of doubt and for purposes of confirmation, but in this work as well as in private practice it appears that cases that may be refracted easily by ordinary means may be very successfully fogged; while obscure cases, like the one just cited, can not be fogged with any reliability of results, so in the final analysis fogging is of very limited value. All fogging systems produce an artificial myopia and are based upon the theory that a myope can not accommodate. This theory is a fallacy, for myopes can and do accommodate, as is proved by the fact that under a cycloplegic, when accommodation is paralyzed, a myope almost always has better vision, showing that the eyes have been attempting to focus and in so doing have increased the myopia. With other well known facts as well as these in view it does not seem feasible to attempt the substitution of any fogging system for a mydriatic.

Cold statistical figures do not show the actual benefits of a service that makes so much for greater physical comfort and contentment, and increases capacity for a better output of work which in turn reacts in a better pay envelope.

Number and Nature of Corrections

Without a volume of uninteresting figures it is difficult to state in exact terms the actual results of this first year's work and, even then, the conclusions must have marked limitations. In a little more than one fiscal year we refracted over 1,100, not including a few cases of disease, accident, and foreign bodies. The cases have been tabulated to give a general idea of the scope of the work with its results, observing the rule, where the eyes are unlike, of basing the record on the better eye. This amounts practically to the same as binocular vision. (Table I.)

The table does not include the considerable number with only one defective eye. The results would probably be about the same as above with an occasional amblyopic eye beyond help because of early neglect and disuse.

In this series it has been astonishing to note the proportion who had no conception of their visual limitations and supposed they were seeing just as well as other people; but it was even more so to find a few who, after the defect was shown and the improvement offered with a pair of glasses, declined all aid, apparently happy in being nearly blind.

Probably the majority of our patients came from those who had vision of 20/20 or even 20/15, but suffered from asthenopia of one kind or another. These, mostly young people, were uncomfortable and, although they did not actually see any clearer with glasses, they were advised without hesitation and worn with great relief and comfort. Had they been occupied with outdoor work they would have had no trouble.

Some of this class revealed marked defects upon examination and it has not been uncommon to find a patient seeing 20/15 O. U. with fair com-

Quarters for the optical department of the Hood Rubber Company have been provided at the plant. The service was immediately in demand and has been extended

fort requiring plus 2 for perfect ease, and several such patients have needed and worn with great advantage as high as plus 6.

The refractive defects here are divided about the same as usually prevail, but at times there has seemed to be a marked over-proportion of mixed astigmatism, usually with off axes. On some days there has seemed to be hardly anything else. These require great care and patience and the

TABLE I.—Ocular Service in 1918-19 of Hood Rubber Company.

Patients	Vision	Corrected Vision
4	20/200 or less*	20/100
9	20/200 or less	20/60
5	20/200 or less	20/40
13	20/200 or less	20/30
20	20/200 or less	20/20
16	20/200 or less	20/15
8	20/100	20/60
5	20/100	20/40
15	20/100	20/30
28	20/100	20/20
19	20/100	20/15
25	20/60	20/20 or over
48	20/40	20/20 or over
88	20/30	20/20 or over

*Some as low as 2/200

retinscope has proved indispensable. The results are highly satisfactory.

Presbyopias have been common and easily handled but there has often been trouble in persuading these patients to wear a correction for distance, even when badly needed. When a distance glass is refused, such a patient will often return quite indignant, with the complaint that when he looks off at a distance everything is blurred and this in spite of the fact that it has been very carefully explained that he must not try to use them for distance as they are for near work only.

Ultimate Results of Service

Of course we have occasional complaints; it would be impossible otherwise, but we feel that, with our heterogenous clientele considered, complaints have been remarkably few. They have come almost entirely from the two extremes of intelligence and we are inclined to think that of the two we have had the more trouble with the higher clerical force.

As another way of finding the ultimate results of this service questions have been sent to some of the foremen asking for reports upon these patients as to their relief from their troubles, their satisfaction, their improved vision, and their increased efficiency in the quantity and quality of their work. The replies received so far have been very satisfactory but not of sufficient number to make them the basis of any statistical deductions Later this method may be extended.

The inability of a worker to make good or average wages may be dependent upon some physical defect, often poor vision, and if this can be corrected it makes for greater efficiency and personal contentment.

The difficulties of showing the actual results of a service of this kind in cold statistical figures are easily appreciated; but in the protection of the employee from greedy commercialism, the greater physical comfort and contentment, the increased capacity for a larger and better output with the opportunity of a fuller pay envelope, this service must have been of far reaching importance and value in the life of every patient, and has contributed to the general prosperity of the concern.

DENTISTRY A PHASE OF MEDICAL SERVICE

By C. B. BRAY, D.D.S., the American Cast Iron Pipe Company, Birmingham, Ala.

IT may well be a moot question, whether or not the Fountain of Youth ever will be discovered, but undoubtedly the searchers for this dream of the ages did a good day's work when they applied dentistry to industry.

The science of dentistry for many years had been considered more or less of a foible of the rich. The man or woman who could go to a dentist was somebody. It was perhaps, in many instances, quite a mark of social distinction to have a gold tooth stuck in front of the mouth; but for the average family, busy with the everyday cares of life, dentistry was not even thought of. Perhaps their nearest approach to it, was when one of the "kids" got the toothache and even then, except in very extreme cases, only hot applications were applied, or a little clove oil injected into the decayed tooth. The dentist and his art, was as foreign to the average man or woman as the wild animals they saw once a year when the circus came through. They simply knew there was "such a thing."

Health Value of Dentistry

Not so now, and the whole change has taken place in the past five to ten years. What is the reason? Simply a discovery of the true value of dentistry as a preventive and a cure for human ills. Men responsible for the operation of industry some time ago realized that the physical condition of the workmen in their shops had much to do with their efficiency. Then one thing led to another until the fact came home to them that a workman's physical condition depended greatly upon the condition of his teeth. The natural thing to do, therefore, was to install an expert dentist in the plant where the workmen with bad teeth would have every inducement to have their injurious mouth conditions corrected. This effected the change referred to; the working-man and his family have not gone to the dentist, but the dentist has been brought to them.

The dental department of the medical service of the American Cast Iron Pipe Company, Birmingham, Ala., was inaugurated four years ago, some time after the Employees' Cooperative Medical Department was instituted. The addition of the dental department was for the same reason as the medical department itself had been formed. The company management had realized that physical fitness determined to an enormous extent the efficiency of a workman, and the medical department was to give each man and his family expert medical care

and treatment at the minimum of expense. After several years' operation, however, it was discovered something was still lacking and further investigation showed that what was needed was a dentist.

Extent of Medical Service

The services of this medical department, which now includes two physicians and a surgeon, trained nurses, operating rooms, consultation rooms, a consulting staff of specialists, two dental operating rooms, and a dentist, are furnished to married men and their families for a standard fee of one dollar per month and to single men for fifty cents a month. The dental department, especially, is popular with the families of married employees, the mother and children in many cases being eager to take advantage of its opportunities. This care of the workman's family has been found very much worth while, because the next thing to health, in promoting a workman's efficiency, is happiness; and no man can be happy if he has an ill wife or children, or is in debt for doctor's fees on their account.

But it is with the workman himself where the really big thing is accomplished by the industrial dentist. He has come to seem almost like the mythical healer of ancient days. His operations are confined to the teeth, but he secures astounding results in almost any part of the anatomy. Men come to him with a chronic case of rheumatism. He pulls a tooth. Presto! The rheumatism, which may have been in the man's ankle at the other end of his anatomy, is gone! From a makeshift, inefficient, dissatisfied, grumbling workman, the patient has been transformed into a healthy, efficient workman who goes about his duties with a song. All by the pulling of a tooth.

But this is only one case. There are hundreds. Men come with indigestion,—bad teeth. Men come with neuralgic pains; in fact, with everything down to and including an ingrown and souring disposition, and the dentist fixes them up by treating their teeth. Is it any wonder dentistry is being hailed with loud acclaim in industry?

Dental Work Free

The plan we follow in this work is simply this: The company employs a man for full time. He goes on duty at eight a. m. and stays until five p. m. Everything is done for the working-men in the way of dentistry. Alloy fillings, cement, extractions, cleaning, etc., are all free. Gold fillings, plate and bridge work, are charged, or rather, a fee is charged to about cover the cost of material. They have the privilege of having this done on company time. The families enjoy the same privilege. This fee is deducted in small payments as the men wish, each week, until the amount is paid. The company feels that the Dental Department is one of the main legs of the medical department; it saves the time lost in going to a dentist in the city which works a hardship both on the company and the men. The company loses the time while off duty, and the men lose both time and wages they would have earned. The industrial dentist has not hurt the man in private practice, but has helped him; for he has been able to educate the class of people that would never have been patients of any man had it not been for the industrial dentist.

I believe the time will surely come when every industrial plant with a medical department will be forced to include a dental department as well. Until they do so, they will certainly not be able to get maximum results from their medical department.

MEDICAL SCHOOL TO BE MEMORIAL

A greater Chicago School of Medicine as a memorial to the city's soldiers and war workers is to be established with the Hahnemann Medical College as the nucleus. Dr. Daniel Russell Hodgdon will be the head of the new institution, and each separate unit will be named for a promient builder of the city. Instruction along the lines of clinical experiment will be provided, and the practical side of education will be emphasized in order to bring the students into closer touch with the world's activities.

OBSERVANCE OF CHILD LABOR DAY

A nation-wide observance of Child Labor Day by church and social organizations January 24, 25 and 26, is being urged by the National Child Labor Committee. Jane Addams in approval of the plan says that one day set aside for the needs of children and urging the furtherance of child welfare as a religious duty would be most valuable. Because certain states have secured satisfactory legislation for the protection of children, it is easy to assume that it is no longer necessary to push child labor reform forgetting the wretched conditions still obtaining in vast areas of the United States.

CORRECTION

Attention is called to the following correction in the prescription of the second ointment given in the "Treatment of Burns," by Dr. W. Irving Clark, Jr., on page 595 of the November issue of MODERN MEDICINE. It should have read as follows.

Vaselin	20.
Lanolin	20.
Antipyrin	.60
Boric Acid	.60
Salol	.20
Iodal or Iodoform	.20
Phenol	.20
$HgCl_2$	.02

INDUSTRIAL NURSING

There has been a definite expression of opinion recently among industrial nurses generally that there is need for uniform standards of service and for better preparation for their work. Employers are seeing similar needs. Industrial nursing is still a field for the pioneer nurse who often takes up her work without thought of preparation other than a hospital training. She finds immediate need for a broader knowledge, which is often fairly easy to obtain if the way is pointed out.

The industrial nurses of the National Organization for Public Health Nursing plan to form an Industrial Nursing Section in the National Organization at the meeting in Atlanta next April The object of this section will be the formulation and maintenance of high standards for service in industry. It is planned to make known to nurses throughout the country the opportunities for education for industrial nurses. Opportunities exist or may be developed in many large centers. Qualified nurses are eligible to membership in the National Organization for Public Health Nursing. Employers are eligible to corporate membership. Associations of employers and workers, or of employees, are eligible to corporate membership.

All industrial nurses are urged to attend the Atlanta meeting and employers of industrial nurses are urged to send a nurse as their representative.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

PROGRESS OF THE PUBLIC HEALTH MOVEMENT IN THE YEAR 1919

THE twelve months which have just passed have not been marked by striking developments in the acquisition of that scientific knowledge upon which the sure advance of public health must rest. The discovery by Theobald Smith of a new microbe causing contagious abortion in cattle, the work of Francis on deer-fly fever, the contributions of Bradford, Bashford, and Wilson to our knowledge of acute infective polyneuritis, and the very recent studies on lethargic encephalitis at the Rockefeller institute are of interest; but they relate to comparatively minor problems in the general field of public health. Nothing of primary importance has been developed in regard to the control of the common contact-borne infections; and, above all, the vast amount of study given to the problem of influenza has been almost wholly barren of results. We began the year with high hopes that the organized resources of modern science would clear up the obscurity which has shrouded this mysterious epidemic on its earlier appearances. We close the year more in the dark than ever.

In the field of food sanitation some real progress has been made. A number of small outbreaks of botulism have been reported, caused mainly by vegetables canned on the Pacific slope, where it would seem *B. botulinus* must occur in some abundance. With this exception, however, the work of Weinzirl on the bacteriology of canned goods and of Rosenau on the general bacteriology and epidemiology of food poisoning would apparently lead to the conclusion that the danger to health from foods is, in this country, comparatively slight.

Our knowledge of the hygiene of the diet has also made real advances during the past year. The studies of Osborne and Mendel on the importance of particular amino-acids in the diet has tended to strengthen the post-bellum reaction against a too restricted diet, and McCollum's work has emphasized more strongly than ever the necessity of supplementing foods derived from seeds and roots with those made up of leaves, containing a higher proportion of vitamines and more complete proteins. In view of the army experience with dehydration a great deal of attention has been devoted to the question of the effect of drying upon vitamine content; and it appears here, as in the pasteurization of milk, that the nature of the vitamine present, the composition of the medium in which it occurs, the influence of aging, and many other factors affect the results so materially that no generalizations can be made. It seems clear, however, that the drying of milk and of many other foods promises to play a great and a useful part in the solution of the food problems of the future.

When we turn from scientific research to practical application, the year 1919 appears to have been a more fruitful one. Particularly noteworthy has been the widespread interest in what may be termed experimental demonstrations of public health technic on a practical scale. General Gorgas and his associates have apparently conquered yellow fever in its innermost stronghold at Guayaquil; and the whole movement for malaria control, which must in the future be recognized as one of the most important public health problems of the nation, has been given impetus and direction through the demonstrations by the International Health Board of the efficiency of drainage, screening, and cinchonization in producing an 80 to 90 per cent reduction of malaria in selected communities of Arkansas and Mississippi.

The Framingham Tuberculosis Demonstration, which is a similar field test of the efficiency of modern methods of controlling tuberculosis by the detection and hygienic care of incipient cases, completes its first three years this winter, and,—the results, though inconclusive, being most prom-

ising,—is to be continued for a further period. The entire policy of the United States Army in dealing with venereal disease during the war was in reality another demonstration,—this time on a grand scale,—of a new public health technic, a demonstration whose success as described during the past few months offers promise of far reaching results even in such modified application as may be practicable in civilian life.

Finally, the Cincinnati Social Unit, the first reports in appraisal of which have recently been published, represents an extraordinarily interesting experiment in health administration and health propaganda as well as in social organization. The inauguration by the American Red Cross of a nation-wide campaign for the development of health centers is another example of current interest in the development of health conservation work along intensive local lines.

From the viewpoint of governmental health organization, by far the most important event of the year was the passage of legislation in Ohio which divided the state into 110 sanitary districts and required the appointment in each district of a full-time health officer and a public health nurse, the appointments to be made under civil service and to carry adequate salaries and a stable tenure of office.

The enactment of this law marks an epoch in health legislation and should place Ohio in the forefront of American commonwealths from a sanitary viewpoint.

To sum up, the year 1919 has witnessed notable advances in the application of the knowledge already at our disposal, particularly along the fruitful line of practical field demonstrations of the efficiency of the newer technic of public health. It has not been marked by equal progress in the asquisition of new knowledge; and the two great problems of pneumonia and of cancer still offer their compelling challenge to the investigator of the future. EDITOR.

STATE LABORATORY WORK IN NEW YORK

By AUGUSTUS B. WADSWORTH, M.D., Director of the Division of Laboratories and Research, Albany, N. Y.

THE Division of Laboratories and Research of the New York State Department of Health is at last housed in an appropriate, modern building, up-to-date in every particular. For those not familiar with the early history of the laboratory a few words in regard to it are of interest. In 1913 the Legislature of the state of New York passed the present Public Health Law, which established a public health council and authorized a sanitary code whose regulations have the force of law; and from that time to the present the laboratory has steadily grown in the extent and variety of its activities, and in the service which it has been able to render.

The Old Quarters

In 1914 the whole laboratory staff—scientific workers, assistants, and cleaners—consisted of only seventeen persons. The work of the laboratory was carried on in an old brick stable and an adjoining two-story frame house with numerous lean-to additions and sheds, untidy in appearance, both inside and out. The old tin roofs leaked copiously on the stormy day in February when the present director arrived to assume his new responsibilities and to take charge of the work.

Sixteen horses were housed in the small stable. The stable man bled them there, and, also officiating as physiological chemist, he carried the serum into an adjoining room and by obsolete methods of precipitation obtained, in some—but unfortunately relatively slight,—degree of concentration, the diphtheria and tetanus antitoxins. Cultures from cases of suspected diphtheria, specimens of blood and of sputum were examined for the diagnosis of diphtheria, typhoid fever, or tuberculosis. Samples of water, collected by one of the laborers on tours through the state, were also examined; but some of the technical procedures followed were not those of the most approved usage, and there was neither a reference book nor even a standard text-book of recent date to be found in the laboratory.

Although conditions were about as unsatisfactory and about as insanitary as they could be, irrespective of the new high standards of public health work which were to be developed in the Empire State with the powers conferred by the new Public Health Law, the prospect was not in any sense a gloomy one, because it was quite impossible to do anything that would not improve conditions.

It is scarcely necessary to describe in detail how month by month, the work of the laboratory was re-organized and developed until now the staff, including the workers at the branch laboratory in New York City and at the laboratory farm, eight miles out of Albany, numbers 208 workers. Before this new laboratory building was in read-

iness every nook and cranny of the old laboratory building, even the chicken coops in which the stableman had kept his chickens, were utilized to house the increasing staff, At one time in this building from 140 to 150 persons were carrying on the greatly increased work. The crowded conditions at last became so intolerable that it was necessary to rent the greater part of the Bender Laboratory near by.

Reorganization of the Health Department

This development of the laboratory was only part of the re-organization of the entire department of health under the new commissioner, Dr. Hermann H. Biggs, who was appointed in 1914 after the passage of the new Public Health Law. Doctor Biggs and the Public Health Council realized so fully the importance of laboratory service in public health work that it was possible to develop the work along lines of the greatest practical value, and the results obtained so justified the work that the hearty cooperation of the Legislature under two different administrations was secured.

The problem of constructing a laboratory building fully equipped for research work was one which required considerable study. Obviously such a laboratory should be equipped for practically all branches of chemical, bacteriological, and pathological work, not only from the point of view of academic research but for the practical purposes of manufacturing biological products as well. The interest of the state architect, Mr. Lewis F. Pilcher, of Mr. Thomas M. Newton, assistant architect, and of Mr. George B. Nichols, chief engineer, was enlisted in securing a simple, fireproof construction. Mr. Nichols with his assistant, Mr. Ralph C. Taggart, gave considerable time and thought to the details of installing the permanent equipment. The new research laboratories of important institutions were visited, among others, those of the Rockefeller Institute, the Massachusetts Institute of Technology, Harvard University, the bacteriological laboratories of Bellevue Hospital, New York City College, and some of the commercial laboratories.

Fig. 2. General view of the laboratory of the Division of Laboratories and Research, New York State Department of Health, Albany, N. Y. Plain in design, as suits its purposes, the front elevation is relieved by the projections at each end, and by the trimmings and wall courses of buff Indiana limestone.

The first plan was drawn up on the unit basis, but owing to the fact that the building, as planned, would exceed the appropriations, it was necessary to make certain modifications, which reduced the size of some of the research rooms and interferred to some extent with the original plan.

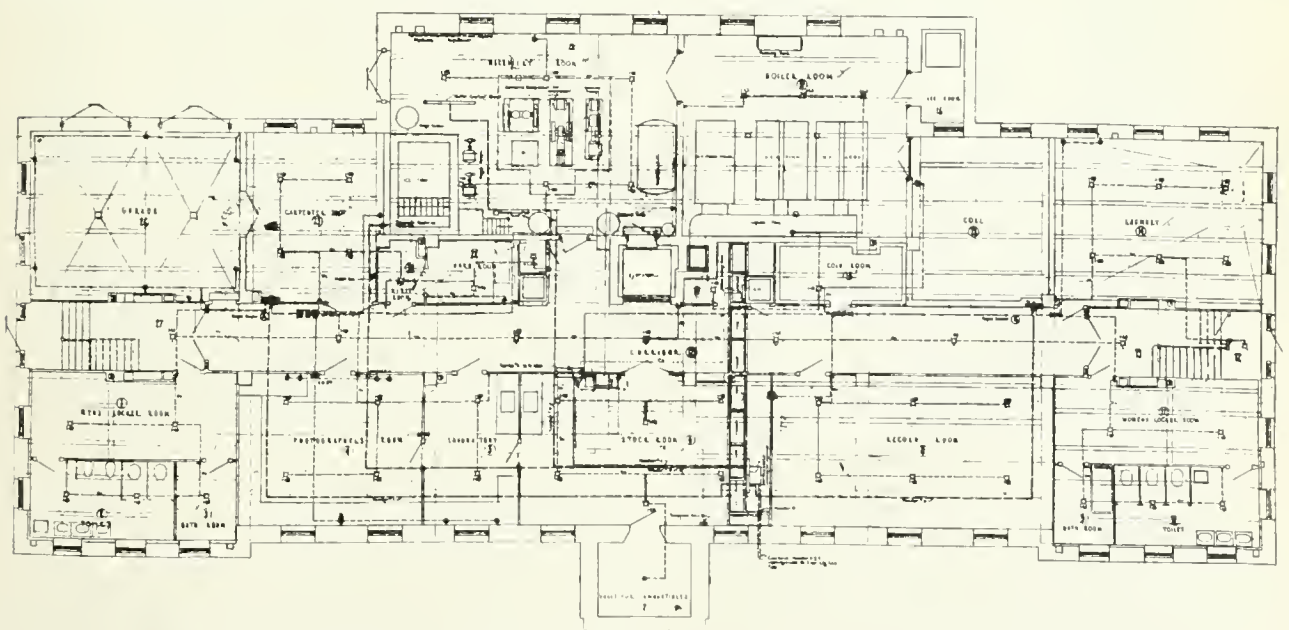


Fig. 1. The basement follows the same general floor plan of the upper stories. Here are located, conveniently grouped for service, the boiler room, machinery room, laundry, machine and carpenter shop, garage, coat room, etc.

The New Laboratory Building

As shown in Figure 2, the architecture of the rectangular red brick building is decidedly plain; but the brick pilasters, the slight projection of the façade at each end of the building, the proportions and the spacing of the windows, together with the trimmings of buff Indiana limestone, all give a suitable appearance to the façade of a laboratory which is to be used for scientific activities and for research.

The construction in general is of reinforced concrete, fireproof throughout. The outside dimensions are approximately 150x50 feet. The building consists of three stories and a basement and the interior arrangement, which is practically the same on all floors, is that of a central corridor extending the length of the building, with rooms ranged on either side.

Location of Units

In the basement (Fig. 1) are located the boiler room, machinery room, laundry, machine and carpenter shop, garage, coat rooms, etc.

On the first floor are the administration offices, the serum diagnostic laboratories, the media preparation, filtering, filling, and boxing rooms, together with cold rooms and storage rooms for special supplies.

On one side of the corridor the second floor space is mostly taken up by a large library, the Director's office and his private laboratory; on the other side are the laboratories for bacterial diagnosis, and for research.

On the third floor are located the chemical laboratories, laboratories for the work of the serums, antitoxin, and vaccine department; rooms for the differentiation of pneumococcus types; for the standardization of the antitoxins; ad-

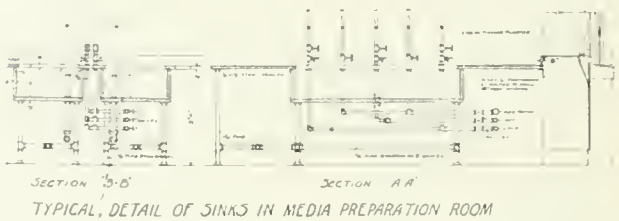

Fig. 4. Typtical installation of sinks. All work tables have five-inch porcelain sinks at convenient intervals.

ditional rooms for the preparation of therapeutic products; and for research. Necessary cold rooms, store rooms, and coat rooms, needed in the activities of various groups are located on all floors. Space also has been assigned for miscellaneous activities, such as a room for x-ray work, another for photography, a cage room for animals, special operating rooms, a rest room for women, and a luncheon room.

The Machinery Room

In the machinery room in the basement is the power plant for running the heating, ventilating,

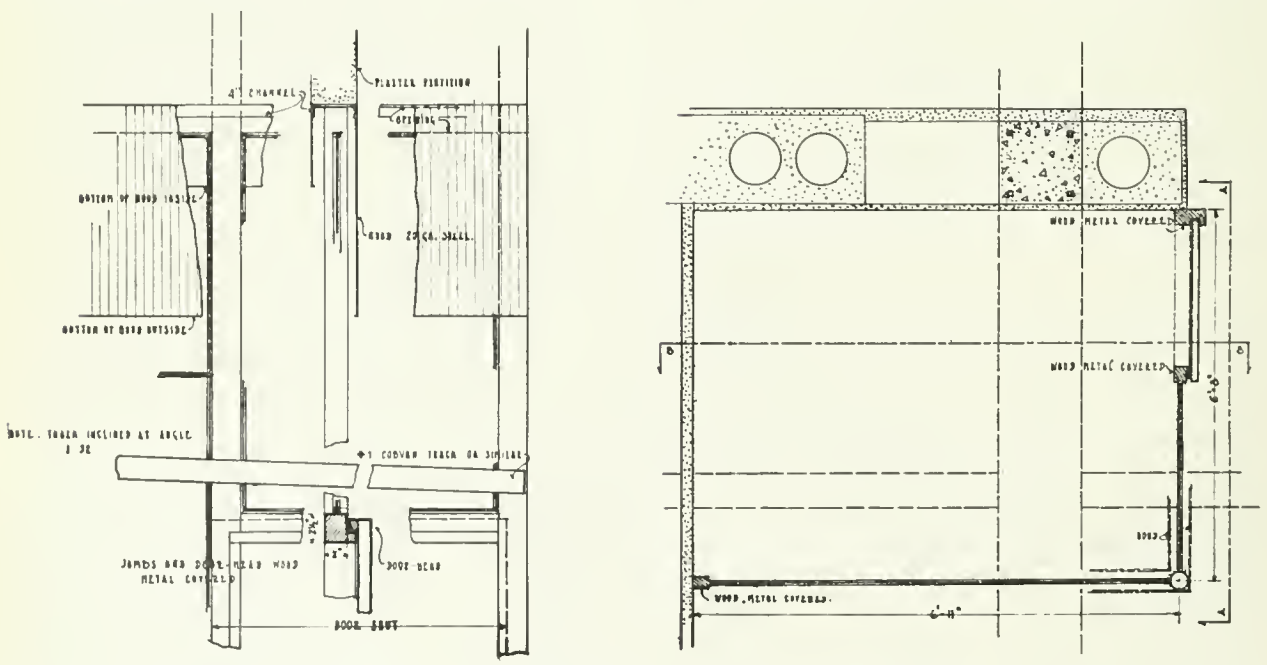

Fig. 3. Floor plan and detail of sterile room. The side walls extend only to within two and one-half inches of the ceiling, leaving an air space. Direct passage of air through this space is prevented by metal aprons.

compressed air, and cooling machinery. Heat is supplied by two low pressure steam boilers, the steam being distributed to radiators that are hung on brackets above the floor in panels below the window, so that every window has a radiator un-

der it. This arrangement prevents the cold drafts of air from the windows, and provides a current of heated air upward instead of a downward current of cold air. Ventilation is accomplished by exhaust fans driven by motors located at the top of the building. There are two separate systems, each ventilating one-half of the building. These can be operated individually and are cross connected in such a manner that either fan can be used to exhaust both systems, when desirable.

High pressure steam is furnished by a boiler carrying between 100 and 110 pounds pressure. Steam at 100 pounds pressure is delivered to the media room for use in the hot air sterilizers. Another line from the same boiler, after passing through a reducing valve, is conducted to the laundry at 60 pounds pressure. A third line, after passing through a reducing valve, is distributed under 20 pounds pressure to the steam baths and fume hoods in the media room, to the chemical laboratories, and also to the stills for distilling water and for alcohol recovery, and stills for research and experimental work.

The machinery room contains a reciprocating vacuum pump, driven by a belt-connected motor. The vacuum system is capable of maintaining 28 inches of vacuum. Pipes connected with this system are distributed to the fume hoods, sterile rooms, and to the bacteriological and chemical laboratories throughout the building.

A reciprocating air compressor, driven by a belt-connected motor, is also located in the machinery room, and air under 90 pounds pressure can be distributed to the sterile rooms, fume hoods, chemical laboratories, media room, filtration room, and other rooms in the building where air pressure is required.

The equipment for cooling consists of a six-ton ammonia compressor, with the necessary brine circulating pumps, tank, and coils. The brine tank is located in the machinery room and is supplied with the necessary cans and apparatus for manufacturing ice in moderate quantities. The cold rooms in different parts of the building are cooled by brine circulating from the cooling plant. The brine is also delivered through

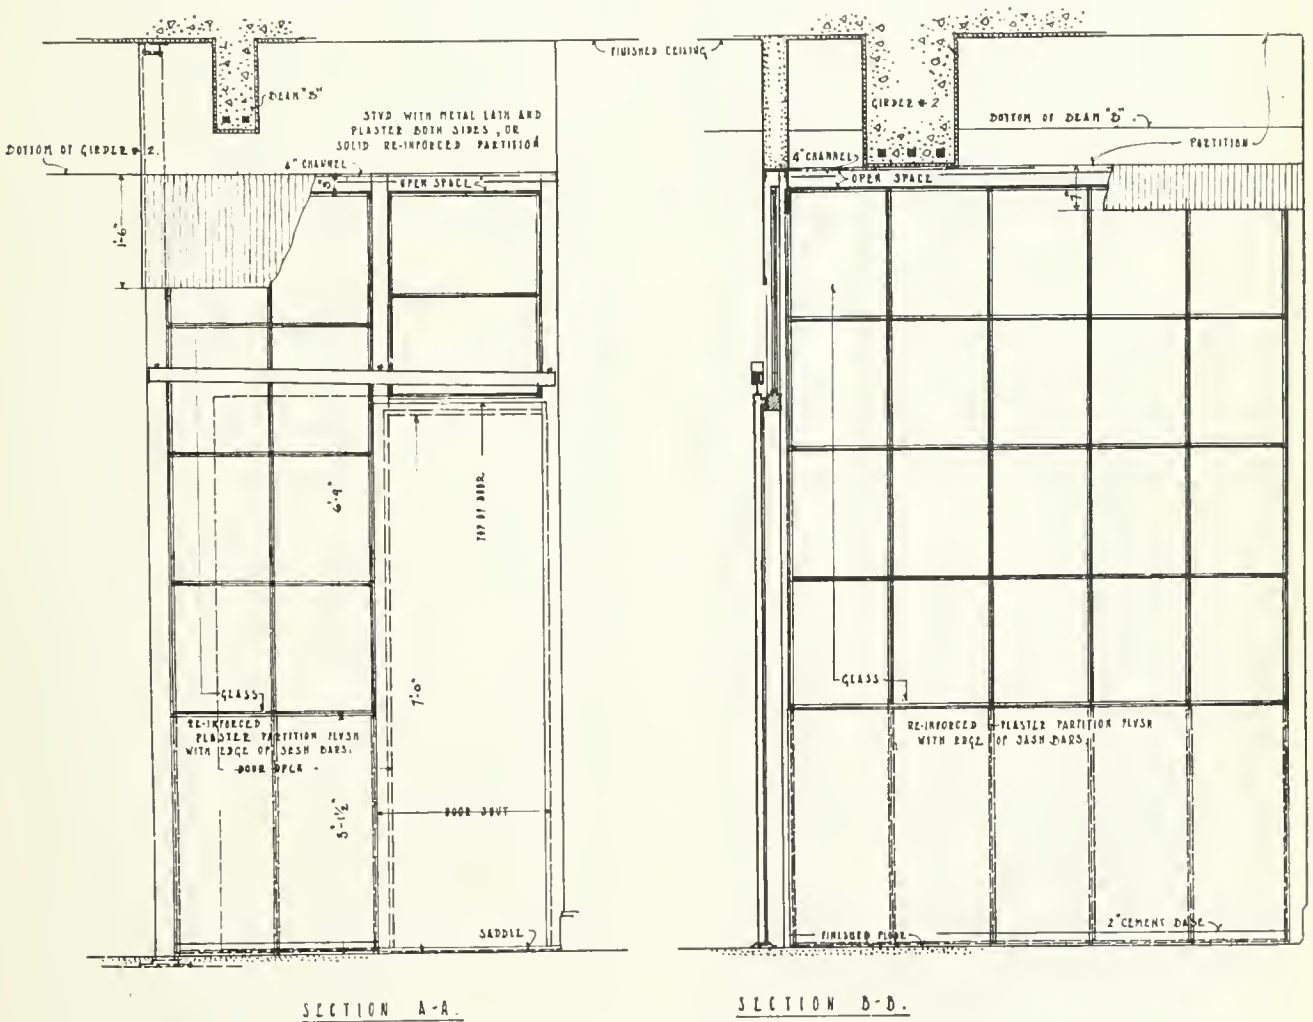

Fig. 5. The construction of the sterile room is unusual and interesting. Two sections are given, showing detail of construction. Ventilation is assured, and air contamination reduced to a minimum.

coils in a tank for cooling drinking water to an automatically controlled degree. On the top floor in the dialyzing room, under regulation, it lowers the temperature of the water in a tank to 35° F., and this tank, in a separate cold room, delivers the cold water to a dialyzing sink so that dialyzation can be conducted at low temperature.

Installation of Equipment

The city supply of water, gas, and electricity is utilized. Large mains and feed wires are installed in order to provide a sufficient supply for all purposes. A six-inch water and a three-inch gas main are provided. The electricity is supplied from the city current in large power and small power units. The electric current for the large power units is 220 volts, three phase, forty cycle. For the small power units and lighting the current distributed is 110 volts, single phase, forty cycle. Special power lines are delivered to the laundry and to the x-ray photograph room; otherwise, the laboratory rooms were wired to furnish in each room thirty amperes; each line is fused for twenty-five amperes, each room having a separate fuse-box. The electric conduits are concealed in the walls except where carried over the table tops to furnish outlets for plugging-in apparatus.

From the power plant the various mains are suspended from the ceiling of the hallway of the basement and by five groups of vertical risers located in chases which open into the hallways; they are thus exposed throughout their course. In the ceilings of the first and second stories supply pipes from these risers are distributed. The ceiling is lowered so that they are all concealed, but they are accessible at all times for repairs through manholes in the ceilings. The drains, of ordinary cast iron pipe, are all exposed under alberene benches which are placed on the outer walls of the workrooms, and lead to vertical waste pipes of vitrified tile set in concrete.

Above the benches the gas, electricity, hot and cold water, and vacuum pressure are distributed around the room. Fume hoods are located in all rooms used as laboratories. They are constructed entirely of metal and glass, the wall of the room where the hood is located being faced with tile. Separate ducts made of vitrified tile, having one outlet at the top and another at the bottom of the hood, extend from each hood to the ventilating system. The fume hoods in the bacteriological laboratory rooms are equipped with gas, vacuum air pressure, hot and cold water, a small five-inch porcelain sink, and also outlets for plugging in electrical equipment. In the Director's private laboratory, in the various chemical laboratories, and in the media room, the fume hoods are further equipped with steam baths. These baths have tops of alberene stone set flush with the table top or floor of the hood.

All work tables have five-inch porcelain sinks located at convenient intervals (Fig 4). A special faucet is located over each of these sinks and will deliver hot water, cold water, or a mixture of the two.

There are special incubator rooms on the second and third floors. These rooms are insulated by compressed cork four inches in thickness which is covered by cement plastering. The rooms are heated by electric resistance coils. The temperature is regulated by thermo-regulators.

All the rooms intended for various miscellaneous work, the laundry, machine and carpenter shop, stock rooms, record rooms, etc., are equipped with the most modern apparatus obtainable. The entire building is provided with a telephone system and an electric clock system.

Facilities for Routine Work

In the top of the building, the stills—water and alcohol—are located, and distilled water is delivered in block tin piping through two lines to each floor of the building and, especially to the large room for the preparation of media and glassware. The arrangement of this room is possibly of special interest. It is provided with a large hood over the sterilizing equipment and with cranes for lifting the baskets of glassware; steam vats for boiling the test tubes after preliminary sterilization; and battery of autoclaves of the Bramhall, Deane type, two with twenty-four-inch doors, two with sixteen-inch, and six with twelve-inch doors. These autoclaves are equipped with both steam and air pressure, and with vacuum pressure so that air can be quickly exhausted. After steam sterilization has been completed, the steam pressure can be replaced by air pressure for rapid cooling without lowering the boiling point.

The construction of the sterile rooms (Fig. 7) deserves mention. It was specially designed to protect against dust. The walls of the rooms are of metal, forming frames for windows down to a point level with the table top in the room. Below this point they are filled in with expanded metal which is afterwards plastered flush with the window frames to form the walls from the windows to the floor. The doors are metal covered, suspended from above, opening and closing on tracks and rollers.

In order to assure ventilation and at the same time to reduce air contamination to a minimum, the side walls containing the windows extend only

to within two and one-half inches of the ceiling, thus leaving an air space. Direct passage of air through this space is prevented by metal aprons. The accompanying views and plan of the sterile rooms (Fig. 3) show that the construction is simple and practical, providing ventilation with comparatively little contamination.

So much of the space of the building had to be devoted to the actual work, that it was not possible to provide both private offices and private laboratories for individual members of the staff, yet a large proportion of the staff require quiet rooms where they can retire for study. In order to compensate for the lack of offices one of the largest rooms is assigned to the library. In the library the standard books of reference and the important journals are kept accessible for all members of the staff. It is expected that this arrangement will provide adequate space and quiet for all.

Extension of Laboratory Service

Attention has been paid to every detail of the equipment in order to have the apparatus, the various kinds of power furnished, and the arrangement of all appliances as modern, sufficient, and convenient as possible. Such completeness of detail would be desirable to have in every health laboratory; in the laboratories of the New York State Department of Health the best obtainable equipment is a necessity. The municipal and county laboratories look to the central laboratory for inspiration and information, and the central laboratory is organized and equipped as a model. No inconsiderable amount of time and effort is expended by the laboratory in Albany, outside of its principle activities of diagnosis and of the production of biological and chemical products, in encouraging development in smaller laboratories all over the state.

The new laboratory building is evidence that the laboratory has given increased service year by year and that physicians are taking advantage of the diagnostic service, and are using the therapeutic and prophylactic products which are supplied. It also testifies to the important place which the laboratory holds in a public health organization.

It is probably apparent to the least observant person of modern progress that there is a strong movement towards a unified, organized, cooperative medical service—a movement which the experiences of the last few years have accelerated. But whatever forms it may take, certain phases of preventive medicine will probably always be based upon laboratory findings, the need of laboratory work will grow with the growth of all the various branches of this socialized medicine, and additional laboratory facilities must be provided to meet the demands coming from directions which are now unforeseen. Also, many research problems of the greatest importance remain to be solved in the laboratory.

CHILD LABOR IN THE UNITED STATES

No figures have been compiled to warrant the recent assertion that child labor in the United States has been reduced 40 per cent since the child labor tax law went into effect, according to latest advices from the Internal Revenue Office. While a marked decrease has been reported in those industries affected by the law, it applies to only a small number of the occupations in which children are gainfully employed. By far the greatest number of child workers under sixteen are listed in other occupations.

There has been a strong movement in many states to increase the school age, and nineteen states strengthened their compulsory school attendance laws in their legislative sessions last year. In several states, too—notably North Carolina and West Virginia—child labor laws were amended to bring them up to the standard set by the Federal law. Many states, however, still fail to provide adequate protection for their children, and efforts will be made this winter to strengthen compulsory attendance and child labor laws to reach those children who do not come within the scope of the Federal law, and to provide for their strict enforcement.

ILL HEALTH A SOCIAL OFFENSE

In an ideal community, responsibility for sickness, like responsibility for crime, would be placed where it belongs and a penalty exacted; anybody's illness would mean a disgrace for somebody, says Dr. William H. McCastline, health officer, Columbia University, as reported in the *Detroit Free Press*. Unnecessary ill health, preventable weakness, should be considered an offense against society. It is truly that.

Doctor McCastline thinks it is quite feasible to provide for the whole public as comprehensive a health program as that which obtains at Columbia, for the lack of which he believes America is at the present time only 50 per cent physically efficient. Two outstanding facts were emphasized by the results of the selective draft: a high bodily average, perhaps amounting to notable superiority of the normal Americans; and a startling number of Americans who are not normal.

A general study of the health and vitality conditions of students at Columbia shows a great number of individual health problems even among selected youths. Ninety per cent of these are easily solved when taken up promptly. Advice cannot be given except on actual data, but community education should see to it that physical incompetence does not result from ignorance. The expense is insignificant. When the cost of John Smith's rheumatism or other disability to the community is considered, the community has a right to take up the matter of his cure through an investigative health service.

Before such a program could be effective, a strong national interest with increased facilities would need to be provided. The state and individual responsibilities should be locally assumed, but all public health efforts should dovetail into a nationalized scheme looking toward uniform state legislation in health matters.

TRACHOMA IN THE CAMPS AND HOSPITALS OF THE ARMY—FROM A MILITARY POINT OF VIEW

By BURTON CHANCE, M.D., Philadelphia.*

THOUGHTS of trachoma, and the fear that it might infect the country, have deeply occupied the minds of American ophthalmologists and sanitarians for the past fifty years. As the disease is found well nigh universally, the admission into this country of immigrants of the lower orders from eastern Europe, Asia Minor, and the Mediterranean provinces; Arabia, Palestine, and Egypt, as well as from parts of Prussia and Russia, regions of the earth where the disease has been known to exist for centuries, has increased the menace excited by the infection imported by the early Irish immigrants at about 1850. Yet, from the investigations by the Public Health Service a number of years ago, it was learned that this country contains certain somewhat isolated areas where the disease exists, and it was found more or less constantly throughout Appalachian America, in some portions of which region the infection was found to occur in as high as 12 per cent of the population, while in others an even higher scale of infection was found.

A Widely Prevalent Contagion

Trachoma has been classed by the Government as a dangerous contagious disease and, because of the widespread prevalence in the areas of the United States alluded to, the Public Health Service established in these sections six ophthalmic hospitals for the treatment of the disease. These hospitals have been maintained in operation for several years and, according to the report of July 13, 1917, during the previous year a total of 19,530 patients was treated. Entire families, including both extremes of life, were found suffering from trachoma. Accordingly, the officials of that service uttered a cry of warning as to the dangers incident to the enlisting into the Army of recruits affected with trachoma, and defined "that it is our duty to prevent the admission to the Army recruits who may spread the disease."

The history of European wars shows that trachoma became a grave menace to the efficiency of the fighting forces by invaliding thousands of men, at one time blinding large numbers; indeed, so great has been the prevalence of trachoma in armies that it has been termed "military ophthalmia." Its introduction into armies has almost always come from the surrounding civil population, commonly from the areas from which recruits have been accepted, who in turn give it back to the people often with increased severity when discharged after serving their enlistment or when they have become incapacitated.

It is said of the Belgian Army that in the first half of the nineteenth century one soldier in every five suffered from trachoma, and it has been stated that in the past century and a quarter, the English, Prussian, and other armies suffered from the ravages of the disease; while during the Russo-Japanese War trachoma was a formidable enemy to be reckoned with in the Japanese army. In the first half of the Great War, an epidemic of trachoma is reported to have broken out in France, having been brought into the country by the African soldiers and laborers; nevertheless, the disease in the army was checked by the quick isolation of all its victims. This report excited the fear that our soldiers might be dangerously exposed from contact with the Allies. The sequel, however, shows that from the care instituted by our Medical Corps and the concentration of the troops in a designated sector, the disease failed to spread among the American forces.

Afflicted Draftees Met With

At the time of the Declaration of War by this Country, in April, 1917, the presence of trachoma was cause for the rejection of a recruit. The Surgeon General's office was keenly alive to the possibilities of the case and early sought to impress upon the military authorities the importance of preventing the admission into the Army of any infected recruit. In the initial regulations for the Selective Service Act, May 18, 1917, the presence of this disease caused rejection, and throughout the War the Medical Department sought to protect the Army and the public by insuring isolation of the infected, as well as provision for their treatment at special hospitals. The Surgeon General recommended that a concentration camp, in all respects like a National Army Cantonment or a National Guard Camp, be established for the treatment of those infected as well as providing for the training of the soldier, with a staff attached to carry out the form of treatment pursued by the Public Health Service at the hospitals at Grayson Springs, Cerulean Springs,

*Read at the Meeting of the American Ophthalmological Society, Atlantic City, N. J., June 16-17, 1919.

and Olympian Springs, in Kentucky; and, realizing that errors in diagnosis might occur whereby a draftee affected by a benign conjunctivitis would seek to avoid military duty by advancing the false plea of "trachoma," that all affected by a suspicious conjunctivitis be retained and committed to hospitals for treatment and held until the course and treatment verified the diagnosis.

In order to exclude none at all likely to be available for military duty, it was suggested that, in the second draft, such infected ones as might properly be classed in the "deferred remediable group" could be accepted with safety pending treatment at the Concentration Camp. And, further, all afflicted, but otherwise qualified, whose visual acuteness was at the standard or, if below, capable of improvement, in the opinion of the opthalmologist of the Advisory Board, if improved by treatment, would be accepted. It was cause for great regret, to those deeply interested, that these suggestions did not receive the approval of the military authorities.

In the Medical Department's desire to spare no effort to cure the disease and to prevent its spread, the methods of the Public Health Service were studied and carried out in a small group of true cases which were operated upon by Surgeon MacMullen and were later sent to duty at the various camps.

Incidence in American Army

In spite of all precautions, it was found that Boards had accepted draftees afflicted, and these were in the training camps to which draftees from infected districts were mobilized. And, further, the sick and wounded reports showed that many were discharged to civil life who, it was feared, might prove to be a dangerous menace to their several communities.

As is well known to all, the ophthalmologists assigned to posts throughout the Army spared no exertion to segregate all suspicious cases of conjunctivitis and, as time went on, such cases as improved rapidly under treatment or were of a doubtful diagnosis were retained in the base hospitals and every precaution was taken to avoid the possibility of contamination; while, from military necessity, those with far advanced trachoma, presenting pannus, scar tissue, induration, and granules on the bulbar conjunctiva, were recommended for discharge from the service. But by June, 1918, according to the "Standards of Physical Examination, Provost Marshal General's Office, No. 75," trachoma fell under the classification of those who "shall be unconditionally rejected from military service."

It may be of interest to know something of the experiences in the armies of the Allies and others, although full reports are not yet available.

Experience in Other Armies

Kirchner of Berlin,[1] from his observations in the Prussian Army up to 1917, declared that, thus far, trachoma had proved to be an entirely negligible quantity in military problems; yet Zimmer,[2] of Avignon, found in ten months' service 27 per cent of his ophthalmic cases to have been thus afflicted, and during his captivity in Germany he observed that 50 per cent of the Russian prisoners had the disease.

Hanford McKee,[3] from the scarcity of cases found during his association with the Canadian forces was led to believe that trachoma has almost entirely disappeared as a military disease.

Sir James Barrett,[4] of the Royal Army Medical Corps in Egypt, made a rather startling contribution, for he records that in 1915, practically none of the soldiers contracted trachoma, and such as were afflicted came from Australia!

Eason,[5] of the Egyptian Expeditionary Forces, in discussing Military Ophthalmia in Egypt, in the period 1915-1918, recorded 64 cases of old standing disease and 39 cases of trachoma, 26 of which were found in Australians. In one's ignorance one is startled to learn that trachoma is prevalent in that but recently discovered continent. Of the 26 it was asserted that only two had possibly acquired the disease in Egypt! This circumstance throws a flood of light on the supposed contagiousness of trachoma amongst Europeans and, incidentally, on the legislation adopted in the various countries with regard to persons suffering from trachoma; for it must be remembered that practically all Egyptians are diseased; and yet, despite the fact that the Egyptian Labor Corps worked for weeks and months alongside the Australian and British troops, and that large numbers of Egyptian orderlies served in the British hospitals, there was entire freedom from infection. Accordingly, trachoma has been practically non-existent as a disease among the British troops in Egypt and Palestine. These officers did not hesitate to declare that with modern habits of personal cleanliness and camp sanitation, trachoma is not actively infectious among large bodies of men and, accordingly, there could be no danger of the army becoming infected in Egypt; and they believed that discharged soldiers infected with the disease would not spread the disease on their return to England.

[4] Barrett, Sir James: Brit. Jour. Ophth., 1919, xiii, No. 2, p. 78.
[5] Eason: Tr. Ophth. Soc. U. Kingdom, xxxviii, 30.

As to ophthalmia in the Turkish army, from figures from one of the prisoners of war camps in Egypt it is evident that trachoma was prevalent among Turkish troops; for, from July, 1917, to January, 1918, in an average monthly camp population of 8,000, among 1,163 cases of ophthalmia, 290 were simple trachoma. Such a record might have been expected since trachoma, next to malaria, has been known to be the most prevalent disease in Palestine.

From the establishment of the organized medical service in the camps and hospitals in America, to January 1, 1919, trachoma was reported from 36 posts, and the total number of cases equalled 860. In only three camps did the number exceed one hundred cases, to wit: Taylor 125, Cody 191, Greene 122; while at Cape May there were 64, and at Pike 69. With these greatest numbers, the numbers at the others ranged from 1 to 45, the total average being only 23! It can thus be seen that the disease was not a problem after all.

It is not at this date possible to obtain the statistics of the overseas cases. As we have already learned from Lieutenant Colonel Greenwood's interesting and graphic reports at the recent meeting of the American Medical Association, trachoma was sought for from the earliest days of the arrival of the forces. In the contagious stages, or when suspected, all cases were sent to special base centers where they were segregated and treated under precautions to prevent the spreading of the disease, and the infected and others were instructed in the care of towels and handkerchiefs. Severe cases requiring lengthy treatment and whose vision was likely to be reduced, were as speedily as possible recommended for discharge and routed back to America. They were passed on and on from one hospital to another until, as was the course in my own cases, they reached New York, or Newport News and, finally, Cape May.

My own army experience with the disease occurred in the service at Camp Jackson, Columbia, S. C., from September to December 22, 1917, and, for the period from May to December 4, 1918, as Chief of the Ophthalmic Section of the General Hospital No. 11, at Cape May. To the Cantonment at Camp Jackson were sent draftees from the Carolinas, eastern Tennessee, Arkansas, and Florida, comprising a goodly portion of the lower Appalachian region. I served on the board of experts in the examination of the draftees and, when the Base Hospital was established, in the wards as well as on the Board. The Committee of Ophthalmology of the Council of National Defense, cooperating with the Surgeon General's Office, had anticipated a horde of reeking cases, so that I, having striven all my professional days to escape trachoma, had visions of returning home blinded and a menace to my family. But either the Public Health Service had so thoroughly cured the eligible young men, or the opthalmologists of the local draft boards had so skillfully diagnosed the diseased lids of the draftees that, up to Christmas, 1917, I rejected only thirty-five undoubted cases of trachoma, and three other suspicious ones of whom I felt safe in classing as granular conjunctivitis. I turned the eyelids of every man presented to me, irrespective of the complaints or the object of the examination. The follicular type was that most encountered, although several had granulations in the bulbotarsal folds, and a few showed cicatrices of the tarsal conjunctiva. I did not see a case of trachoma with pannus. Several of the cases had quite active symptoms. These were isolated and treated at first in an early established "Field Hospital," but later on, when the Base Hospital was opened, a ward was set aside to receive them. Here were pursued the commonly accepted "mechanical measures," to which I added the swabbing of the upper retrotarsal folds with glycerole of tannin. At that period the subject of the disposition of the trachomatous was not yet settled. In recording the cases I made every effort to impress upon the rejected men the importance of the disease and directed them to report to their physicians and to their local boards.

Incidence in Overseas Men

At Cape May I received a small number of patients from posts in America, but the rest were returned overseas men. Many of the men had enlisted and had gone over with the First Army, while several had gone over with the Canadians, and some had enlisted in British organizations. More than one man declared that his eyes first became acutely inflamed on the voyage to France. Up to January 1, 1919, 64 cases were reported as having trachoma. Of these I wish to speak of 26 undoubted cases, only 3 of which were unilateral. Every man declared that the disease arose after entering the Army; yet, on closer questioning, admitted having had ophthalmia in past years. Only 4 presented the follicular type solely. The others exhibited cicatrices in the tarsal tissues; 5 showed pannus and involvement of the corneal tissues; 3 showed granulation of the bulbar conjunctiva. One had large exuberant granules, the like of which I remembered as having seen years ago before the stringent rejection of immigrants became enforced. He was a horse ranchman; he was evidently suffering from a re-

crudescence of the disease because he admitted having had previous attacks.

None had active ulceration of the cornea. One had dacryocystitis. One of those with pannus was a negro from Maryland. None of the other patients, those who had had an eye excised because of injuries, etc., exhibited signs of trachoma. I saw no signs of the disease in any commissioned officer under my care or observation. Two patients were Indians from the Southwest.

I had the men isolated in rooms as far away as could be from healthy men until it was possible to obtain two cottages adjacent to the hospital. By this time Lieut. William A. Krieger, and Lieut. Warren Reese were assigned to duty at the hospital. They alternated weekly tours of service. On Mondays I made a regular tour of inspection of the quarters and examined each patient, directing the treatment, and recommended the disposition of the cases. All patients in the Ophthalmological Section were given frequent douches of sulphate of zinc. The routine treatment of the trachomatous consisted of repeated daily cleansing of the conjunctival sacs with weak bichlorid of mercury solutions, and in the active cases mechanical measures were persistently carried out. Two or three times a week, boroglycerid and tannoglycerid applications were made to the fullest extent of the membrane, with extremely satisfactory results in most cases. Expression by Knapp's roller-forceps was practised by Lieutenant Krieger with great benefit; one case, with abundant and prodigious granulations, from which the man had not been able to open his extraordinarily swollen lids for several weeks, yielded almost miracuously after thorough expression. Except in this last case, none presented unusual symptoms; at least, nothing beyond the like of which I had had at my hospital in Philadelphia. I did not regard any as worthy of the operation for the excision of the retrotarsal folds.

The men were kept under surveillance until the discharges became mucoid and the follicles absorbed, with sufficient regression to justify "S. C. D."

AID FOR INSTITUTE OF TECHNOLOGY

A new plan of cooperation which may have far reaching effects on the educational and industrial structure of the nation has been evolved by the Institute of Technology, Boston, Mass., in its campaign to raise new endowment funds so that faculty salaries may be increased. The plan puts the institution into the position of being retained in a consultant capacity on an annual salary basis by the various industries in return for which the Institute will permit the corporations to make use of its extensive library, files, and plant, and to consult with members of its staff and faculty. In addition, it will place at the disposal of these corporations a record of the qualifications, experiences, and special knowledge of its alumni, and will advise as to where especial knowledge and experience in any given subject may be obtained.

WILL DISCUSS INFANT WELFARE

The medical, philanthropic, and administrative phases of infant hygiene will be dealt with at an international congress to be held in London, in September of next year.

STUDYING EPIDEMICS IN POLAND

Members of the interallied medical mission which is making a study of typhus and other epidemic diseases in Poland are: Doctor Visbeco, chief of the French Military Health Service; Col. Hugh S. Cumming, representative of the health service of the United States; Dr. Aldo Castellani, of Italy, professor in the School of Tropical Medicine, London; and Dr. George S. Buchanan of the English Ministry of Health.

APHORISMS ON HEALTH

The student health service of the Ohio State University furnishes free medical advice and treatment to students, but goes farther than that in its aggressive health propaganda which emphasizes that the great hope of modern medicine is the *prevention* of disease. Their literature contains advice against worry attitudes, excesses of any kind; it outlines rational every day practices in the interest of physical well being, and contains such health suggestions as the following:

"When you feel you are losing ground, and every trifle magnifies, annoys, and irritates, *relax* for a few minutes each day.

"If you would be healthful and efficient, keep your head up, shoulders back; stretch your neck; try to touch some imaginary object with the top of your head. Make it a habit to keep the back of your neck pressed against your collar. Watch the result."

LABOR PROBLEM IN BRITAIN

The necessity of better housing and better shop conditions in British factories from the standpoint of sanitation which has long been apparent has finally materialized into a determination to standardize shop conditions. This is due, undoubtedly, to the protests of returned soldiers who have lived a life of cleanliness out of doors, and who now refuse to reenter the old shops which do not afford even ordinary comfort.

"The very handicaps which stand in the way of rapid sanitary reform, also operate against reform of mechanical process and equipment. Most plants are built compactly in the hearts of cities where expansion is costly, and contingent upon the willingness of the owners of adjacent property to lease or dispose of their holding," says Burwell S. Cutler, Special Trade Commissioner, in *Commerce Reports*. "Operators also fear that using space for elevators and light and air shafts will cut down production. They are now much more concerned in crowding their floor space with productive machinery of the newest types so as to compensate for the loss of man-hours by the inauguration of a 48-hour week. But employer and employee are together working out a new industrial relationship, a new type of joint responsibility as between men of the same race, the same nature, and a thousand years of common history. They are homogeneous and they seem to understand each other at bottom."

HEALTH CLINICS

FLORENCE MEREDITH, M.D., Director New York Health Center for Women and Girls; Consultant, United States Public Health Service; Medical Examiner, Wellesley College; Instructor in Surgery, Tufts College Medical School.*

WE are of necessity thinking along the lines of reconstruction of health after the destructive blows of warfare that fell not only on the men themselves, but often upon the women who replaced them in the industrial and business life of the country. The need for reconstruction on such a large scale has brought more vividly to our minds than ever before the very great gain in human happiness and wellbeing if evil of all kinds, including physical, could be prevented. Every medical and social organization has been impelled to do its share in this great task of prevention. It has been tackled from every possible angle.

THE SCIENCE OF HEALTH

Hygiene is the science of health. It is not disease detection merely, nor even disease prevention. It presupposes health conservation and health promotion.

That the people want health and a health point of view is evidenced by their cooperation once their interest is aroused.

That they do not always get what they want from the physician is shown by the popularity of cults that do without doctors, substituting an esoteric philosophy of life for scientific care.

The Health Clinic practises health conservation, and promotes health by education before illness has arisen.

Health Maintenance the Program

Plans for the actual permanent maintenance of health, such as we have developed at the above mentioned center,—looking farther than the cure of disease, and even farther than its prevention, had not, so far as I know, been developed until March of this year, when the Health Center was evolved. We believe that the next step in medicine to be elaborated by the medical profession, is that of developing methods which seek not so much to avoid an evil thing, such as preventive methods seeking to avoid disease, but to get and keep a good thing,—health. So, rather than speak of prevention, we speak of conservation, putting the question of disease still farther behind us. The success of the Center is the vindication of our aim. We have held repeated conferences at the Center, attended by women physicians from all over the country, and we have demonstrated to their satisfaction, as we have to our own, that health is an ideal toward which even the humblest will strive if it is properly presented to them, and that education toward health produces results not to be hoped for from education against disease.

A number of ideas for the further extension of health education have risen as a result of this experiment. It is of course first necessary that doctors realize the necessity and desirability of more individual health education than has ever been thought practical in the past. Second, it seems essential that other centers such as the one in New York be started all over the country, as has been done in a number of places. It seems especially desirable that hospitals themselves should establish health clinics, to do this purely medical work for which strictly medical organizations should be responsible. A very natural conclusion is that if we are to have health clinics we should have "health doctors," those who specialize more or less in the care of the well.

Health a Personal Objective

Before presenting the work of the Center, we may look over what is already being done by the medical profession apart from the cure of disease. First, it has been doing a great deal for many years toward public health, and no one would question the importance of beginning there, the remarkable way in which this work has been done, and the equally remarkable results that have been attained. In no other nation in the world is public health so safeguarded. Public health work is of necessity done very largely from the point of view of prevention. It deals primarily with populations as a whole; and secondarily, with the individuals as parts of that whole. Then we have tried to prevent disease in other big ways, dealing with the health of the factory worker, for example, as a great whole, and trying, by improving conditions in factories, to improve the health of the workers in them. Housing has received much attention, and we have tried to promote the

*Read before the War Work Council, Young Women's Christian Association.

health of individuals by improving the place in which they live. Desirable as are all these efforts, we have often felt that there is a weak link in the chain somewhere, for those who work in the most ideal factories and live in the most model tenements are not of necessity the most healthy individuals. The reason is, in our opinion, that we have tried to give something,—health,— to those who did not know enough about health to care about it. Now it seems plain that if we can take just one individual and show him in his own life what health will do for him, actually demonstrate to him that he is a more efficient and happier man with health than without it, and can show him what it is that makes the difference between health and the lack of it, we shall have placed in his heart a desire for health which will make him go after the conditions of health himself, rather than turn away from them when they are offered him. The work of broader scope should certainly proceed, but unquestionably it should be supplemented by definite work with individuals. By far the greatest need at the moment, greatest because least realized, is for a greater personal appreciation of health, and knowledge about it gained through education imparted by the medical profession to individuals.

Health Habits to Be Acquired

We have seen that illness is a personal matter, but not that health is too, that it is very largely dependent on individual habits of living. Public health demands first that everyone so live as not to be a menace to the health of others, and it is now demanding that he live so as to avoid disease himself. If we could only demand, too, that he live so as to be at his own physical best constantly, what a gain would be made in the sum total of human welfare!

In the past we have been more or less excusable on the grounds of not having any very definite information to give individuals, but there is no such excuse now. We have a number of well established laws of health applicable to practically the whole population, and there are hundreds of others that can be formulated for individual cases.

The work that most nearly approaches health education at the present time in hospital work is that done in ante-partum clinics and in baby hygiene clinics. There should be just as thorough work done in health education, not disease education exclusively, for those of all ages of life. Sex hygiene means everywhere the avoidance of venereal disease; industrial hygiene the avoidance of occupational hazards, and so on. About the only group to use the word hygiene to mean health is the dentists. They do not urge the use of the tooth brush to avoid toothache or false teeth, and do not even talk a great deal about pyorrhea. They do stress the advantages of good teeth and tell us how to keep them. They have carried on splendid propaganda; as a result, every growing child knows how desirable it is to keep his teeth in order and knows how to do it. Have we been equally zealous in spreading the knowledge of the value of good feet, or good eyes, or a good digestion, and can we as truthfully say that the public knows the advantage of these things, and of many others within our realm, and knows how to keep them? The wide prevalence of a state of being half alive is certainly partly the fault of the doctors in whose care is theoretically if not actually the health of the populace.

While Gorgas announces the final wiping out of yellow fever, a doctor from California announces that 65 per cent of the population of that large state belong to cults that do without doctors. We might as well face the fact that if these people got what they wanted from doctors, not only cure from illness, but increased everyday happiness and efficiency through improved health, they would not do without them. These people are not all feeble-minded, as we often think. They want health and a health point of view toward life, and they go to what seems to them the most promising place to get it. We can give them what will be of more value to them than an esoteric philosophy of life, if we will take the trouble.

The Practice of Health Conservation

There are a certain few physicians who are doing this. While practising internal medicine they are virtually practising health conservation. They recognize the fact that the very greatest opportunity of producing health is by means of health education before illness has had a chance to arise. They take only as many patients as they can give this care and they succeed in keeping them well, as the sleek, all-enduring bodies of the youth of either sex and the well preserved old people in these families, usually those of wealth, indicate. They are seldom ill, seldom have to be given medicine, and if anything untoward happens to them, they are promptly referred to a specialist in the disorder to which they succumb. Such care ought to be possible somehow for all.

It was on this theory that special provision was needed for health education of the individual, that the Health Center was opened. And it is for the further extension of this work, in other centers and in hospitals that I am speaking to-day. There are probably millions of individuals in the United States who could never by any chance afford to have a private physician even in illness. For

them we have provided clinics where they get the best of medical attention free; but if they happen to be well or nearly so, and cannot afford the expert care of the few physicians in every community who would give them anything approaching adequate health education, they are left to their own devices in regard to remaining in health. For these millions should be provided some form of individual care in health, as well as for their care in illness. So far as I know this

Fig. 1. In the New York Health Center for Women and Girls many for the first time learn the relation of habits to health. They are instructed as to their needs and helped into the right ways of living.

extension of hospital work to include health education has not been tried or even mentioned yet, but that it is a feasible plan I hope to show in a brief outline of the work of the New York Health Center where the plan has been carried out under private auspices with great success.

Function of the Health Clinic

There are some advantages about having the work done apart from a hospital, if private organizations can be induced adequately to support such clinics. The chief advantage is that it can stand more definitely for health if it is not under the shadow of an institution intended primarily for the care of the sick. This tends to put the emphasis on the right point at once and makes no special efforts necessary to shift it on to health, as would be the case in the hospital. The only efforts we have had to make have been in the direction of bringing girls to realize that even though we are doctors the well body interests us in this case as much as the sick ones. Outside of a hospital we probably draw more of the sort of people whom we really wish to reach than would be the case in the hospital clinic, where a larger percentage would attend of those already "hospitalized." There was a tendency in the beginning for the girls to consider our center another kind of clinic for the sick, until we adopted the phrase "to keep well girls well." This objective seems to me scientifically and economically the highest aim we can ever hope to reach, and one not so remote that it is not worth trying for. Most of the girls who come to us now have no particular complaints to make of their health. They know they are going along blindly, and wish to be enlightened; or perhaps realize that their physique does not match the life they are called on to live, and wish to get a better balance between the two.

But our work is purely medical and could be done as well as a regular part of a hospital. The fact that social and other organizations have been so ready to take up medical work when it has been presented to them by the medical profession, or even when they have themselves planned it, is vastly to their credit; but in the question of health conservation, doctors should do more than merely instigate an interest in health for other organizations to carry out. They should also carry out a large part of the health programs themselves under their own charge in an institution dedicated solely to medical science, where the public would know where to find it, if it were there, and where health education could be further elaborated under the direct backing of science.

Fig. 2. The most painstaking general and special examination searches out all possible sources of trouble, the soundness of advice depending upon a complete knowledge of the facts in the case.

Even then the cooperation of public spirited institutions would be as necessary as ever. The fact that hospitals have all the equipment ready and lying idle in the evening, the very time when a clinic for well working people should be held, makes it seem quite possible to establish health clinics without much additional trouble. Another advantage in having the clinic in the hospital would be that the facilities would be at hand for the most extensive diagnoses. Referred patients

would not be put to the trouble of hunting up another place, even if they had to come at another time; and they would not have to get acquainted with another institution and another group of officials which, strange as it may seem, is often one of the reasons why referred patients do not "refer." The hospital clinic would be more generally known to the public, and be definitely understood to be free, which disadvantages have to be overcome in the free private clinic or center.

Fig. 3. The régime is always adapted to the individual case. Collective methods are often far from being corrective methods, especially as related to heart conditions.

Our center is free to all women and girls who work in any line,—business, industry, home, or profession. At first we made special efforts to interest the girls we wished to reach by giving noon-time lectures in factories and stores and evening lectures in working girls' clubs; but in less than a month we found that for this purpose they were quite unnecessary as we were booked up three weeks in advance all the time. We continue the lectures however, for educational purposes, to interest girls in their health, advising them in a general way, and urging them to go to their physicians for further individual advice, to find out which way they are headed.

Our method of health education is based on a complete physical examination, carried out in great detail. All possible data are obtained in regard to the past and present condition of the patient, family history, working and living conditions, mental status, and her needs of all kinds. We do not do all the special tests for disease conditions; tests are made for only those most commonly found unless there is some indication of their necessity, in which case the girl is referred elsewhere for the more elaborate tests. In order to be scientifically sound, health education should be based on nothing less than the most accurate available knowledge. It is only in dealing with groups that general rules are of any use, and then only because they will probably benefit the majority far more than they will hurt the minority.

The case history we believe should be taken by the doctor herself whenever possible, as it seems to tend toward greater accuracy. We also prefer to do our own recording in order to do away with a third person in the room, which we never permit except in the case of visiting women doctors.

A questionnaire in regard to living and working conditions was formerly filled out by a social worker, but we found that all the data thus obtained came out naturally during the doctor's examination and could be recorded by her as it was given, rather than to subject the patient to an extra questioning. The importance of the facts along this line is not to be underestimated, however, as is evidenced by the strange things which sometimes appear in this connection, without which the key to the patient's condition would be lacking.

We have also on our staff a specialist in mental conditions, who often solves the problem of lack of response to all treatment and succeeds in getting rid of the faulty mental habits at the bottom of the failure. She is a physician who does not read abnormalities into every case, but puts her emphasis on mental health, as we do on physical, and the habits of mind necessary thereto. Not

Fig. 4. Percussion of the liver constitutes a part of the routine examination. A health program first eliminates the possible disease.

every case is referred to her, less than 10 per cent, in fact.

We are in touch with dietitians who, in case of under or overnourishment, compute calories in an average week's menu. The weekly diet records are used for the purpose of determining chemical content more often, however, for the purpose of establishing a more nearly balanced ration than the average working girl is in the habit of getting.

Special diets for pathological conditions we do not handle here.

An orthopedic examination is given to every patient in which posture and feet are examined, measurements taken and muscle-strengths tested.

It will be seen that we endeavor to leave no stone unturned to find out how to improve the health of the girl and make it more secure. If any girl does not feel entirely fit, shows any signs of giving way under her work, or simply wishes to be sure that she is on the right track, we want to be able to give her sound advice. We often have girls who are working in the day, going to evening school, and doing some of the family housework, who realize that they are going to endanger their health if they are not careful, and who come to the Center to get advice as to the best way of putting in their time to their advantage in all respects, what they are safe in continuing and what changes need to be made in their *régime*.

Health Program Planned

When every bit of available data is in, the next step is to begin the education of the patient. In order to omit no detail, we often begin at the beginning of the history and follow it through point by point, and explain to the patient whatever seems wise. It will be found rather difficult to talk clearly in untechnical language on subjects usually discussed in purely technical terms, and there is some danger of over-educating the patient; that is, of filling her mind with a mass of undistinguishable facts out of which she gets nothing but confusion. Provided we recall that we are not giving a course in medicine, but trying to give rules for health intelligible to laymen, we shall not get into trouble.

Fig. 5. Palpation and the usual laboratory tests afford data as to the integrity of the kidney.

Fig. 6. Postural defects are searched for and charted. They are made the objects of especially devised corrective measures.

All recommendations are preferably to be made in writing, making sure that the girl understands just what is meant. We use a special blank card, with spaces for the recommendations to be written in and spaces for the girl to check at the end of each week when she has followed the advice that week. We find that adults as well as girls are interested in keeping tab on themselves in this way. Although any grading on medical and physical findings is far from accurate, we use the grading system on account of its psychological effect on the patient. We also grade them on their habits. Both of these grades they have the opportunity to raise to a higher one at any time when they are examined afterward, if they show an improvement in either direction.

The Health Point of View

The improvement usually shown in both respects is often rather miraculous; it is not to be accounted for entirely on the grounds of new and better ways of living, but often largely due to new and better ways of thinking about herself and her health. The result of education toward health is thus partly psychological, and not at all to be despised on this account. The physician who is attempting to educate individuals toward health must be rather more of a philosopher and psychologist than we often are, for the human equation is to be reckoned with in the practice of medicine when it is dealing exclusively with advice rather more than when giving out pills and prescriptions. Anyone who has ever tried to get a patient to alter even one point in his manner of living knows that getting him to do it is by no means as simple as telling him to do it. The teacher of hygiene should know people very well indeed, and at the same time he should know himself very well, what he thinks and why he thinks it, and how to make others think it, too.

In order to provide facilities for the carrying out of our advice in regard to exercise we have in our building a gymnasium, with four physical directors for instructing patients in the use of certain exercises which in a large proportion of cases are found to be necessary as a supplement to ordinary everyday activity. We have it under our own roof because if the girls were sent to regular gymnasia they would be given only general exercises, and because they are not sufficiently far from normal to be sent to orthopedic corrective classes. We have found certain exercises necessary for well girls. For example, abdominal muscle exercises to maintain correct position of the abdominal viscera are a necessity for many quite normal people, especially women, since Nature usually fails to teach us abdominal muscle control automatically. We have not yet been long enough upright. Good posture, too, is essential to health; if not natural it should be taught, and taught much more definitely than is usually the case in gymnasia. Exercises for both

Fig. 7. The patient is made to see the relation of good shoes to good posture and, therefore, to good health. From this viewpoint the prevailing style does not weigh against comfort.

of these purposes and a number of others can be classed with health habits, and taught under the physician's direction.

Girls are taught individually, not in classes, a different set of exercises being mapped out for each girl, or perhaps the same exercises in a different amount or order. They are assigned to our gymnasium for not more than a month usually, and then we try to get them into other permanent gymnasia. We want to keep them only until they have had their taste for activity cultivated and have learned their own need, including the special

Fig. 8. The well poised body in action is the body beautiful. Many of these girls gain for the first time the positive joy of health.

exercises, and especially their own powers. They are usually quite afraid of doing themselves some injury through exercise at first, and we frequently examine them directly after exercise, both to determine by the heart action that they are not over-taxing themselves, and especially to allay the girls' own fears.

Girls Learn to Play

Recreation is also carried on in the Health Center and outside, after having been definitely prescribed for each girl. Our recreation leader cooperates very closely with our medical aims, at the same time making very fair athletes and good sports of the girls. We endeavor to get the girls into permanent athletic clubs as soon as possible, as we wish to continue the educational work with new girls as far as possible.

Social workers can be of great assistance in connection with such a center, through looking up all the aspects of the life of each girl which bear on her health, and helping her to make any adjustments which will result in better carrying out of health advice.

We do not prescribe for any pathological conditions, unless we believe the condition is curable by healthful living alone. If any other treatment is necessary the girl is sent elsewhere. Many girls who come in considering themselves simply "ailing," as so many working girls are, find that they need treatment other than hygiene. The function of the Center is thus also that of a clearing house, to weed out those who do from those who do not need more than healthful living.

Of course, we do not keep as a patient any girl who is in the hands of any other doctor or hospital unless requested to, as sometimes happens. In cases we refer elsewhere, all treatment is withheld until the further diagnosis or treatment is

completed. Occasionally at the request of those giving other treatment we prescribe a general hygienic *regimé* to be carried on simultaneously, as, for example, in connection with treatment of the eye or ear, or with the endocrine gland treatment of obesity, or the medical treatment of gastric or intestinal conditions.

Educational Features of Clinic

It will be recognized that hygiene has two functions, that of an independent method of maintaining health, and that of an accompaniment to other treatment. Special and general health education is always necessary along with other treatment before the best results can be obtained from either medicine or surgery. The health clinic is, however, not always the best place for this education to be given, in special cases it being distinctly the rôle of the specialist in charge of the case, who should be if he is not, the best arbiter of the hygiene applicable to his special variety of cases. But it often happens that this hygiene is no different from that applicable to the same individual under other circumstances, in which case the health center is glad to advise her.

Healthful living, which is sometimes an alternate to other treatment, should always be an adjunct to it. It should be used often as a preliminary to other treatment, in which case it will sometimes be found that the other treatment is unnecessary after all.

In addition to referring cases to others, we frequently have cases referred to us from other clinics, factory hospitals especially,—patients who had applied for treatment but for whom there seemed to be nothing to do; or patients to whom drugs had been given repeatedly for the same condition, for example, dysmenorrhoea or constipation, that the doctor was glad to find a group with time and patience enough to get at the cause of the trouble in some unhealthful condition of living.

It will be seen that this method of teaching personal hygiene is making it a very different matter from the dull, futile affair it has been in the past. That so personal a matter as health should have been handled entirely collectively, when handled at all, and that so fundamental a thing as right living should have been, and still should be considered so casually, is hard to account for. But unproductive as has been any method tried in the past, we are blind if we cannot see the possibilities in individual education, given somehow or somewhere.

The public may discount entirely any general information they may receive about health, but they will hold a very different point of view when the same teaching is given individually. If they are sure that after having examined them thoroughly, a scientifically trained person is of the opinion that they would be better off for bathing every day, for example, and are given a good reason for it, one that they can understand and are told just what sort of bath to take, they are usually very eager to carry out the advice. Even on the rather difficult subject of the use of cold water, internally or externally, and the wearing of un-deforming clothing, I have found pathetic little factory girls quite willing to conform to the advice given, when such advice was given for themselves personally, and by one who obviously had nothing but their own good at heart. A few such girls, doing piece work and earning more money as a result of the instituting of better habits, prepare the ground for the successful planting of good habits in other girls, whether it be for less candy and more vegetable, or the substitution of dancing for crocheting, or *vice versa*. Even though girls have fallen rather far below the normal on account of their failure to live up to health standards, they are seldom so far away that they cannot be greatly helped by a survey of their health according to this educational method.

Health Advice With Assurance

Of all the causes of failure to help, the commonest of all is weakness of confidence on the part of the doctor in his own advice, that is, provided the diagnosis and the advice were right in the first place. If the doctor himself is sure of what he is advising, that it is going to make the individual stronger, happier, and more efficient, he can do a great deal to move all obstacles in the way of successful following of his advice. We have in the past given advice in regard to hygiene tentatively, without assurance, and oftener than not have never tried to find out whether results have been forthcoming. Perhaps this has been due to our not having felt the responsibility for this sort of advice as keenly as for medical or surgical treatment.

We have not held ourselves quite as responsible for the keeping people well as for the curing of them. It has not reflected upon us at all if a family in our care is ill half the time. To be sure it may not be our fault, but again it may. The Chinese method of paying the doctor only while health is maintained would not be practical in this country, for oftener than not the physician who is doing his best to teach health does not receive much cooperation from the patient; and too, the exigencies of circumstances in this country often compel disobedience to known laws of health. But

we should expect and demand results, when we give any kind of advice, and to that end use every resource at our disposal for making our recommendations take hold. If advice is worth giving it is worth having it followed. We should be just as positive on this matter as we are when giving a prescription.

The Group Through the Individual

As the examination on account of its thoroughness requires considerable time, a large number of patients can not be reached in any one clinic, unless a very large staff is maintained. For this reason the *per caput* cost is rather high; but, as each patient is the center of much educational work among her family and associates, we can feel justly that it is not as high as appears on the surface. For example, one girl from a boarding home who had it explained to her that she would improve her health by eating less hurriedly, got the whole group of 125 girls in the home properly to masticate and enjoy their food. Drinking water more and tea and coffee less, have become habits among several large groups who have been educated indirectly through girls who have been improved thus, these facts having been reported to us by the women in charge of the groups. A factory restaurant manager was persuaded to make use of more vegetable and less meat, the former having been found lacking in home dietaries where the latter is not, and indirectly much educational work was accomplished. A store requiring high heeled shoes to be worn by its dressy saleswomen was influenced to withdraw this demand by one of its women after she had learned the unfortunate results to those who have to be on their feet all day of wearing shoes no better than those of the Chinese. While it is desirable in the case of those seriously ill to spend large amounts *per caput* in order to restore health or save life, such expenditure is equally justifiable in health educational work, as is already realized in baby hygiene work. The death rate among babies has been decreased in this way, but not yet the sickness and death rate among adults.

The individual health clinic will unquestionably fill a gap that has long existed, whether it be carried on in the hospital, public or private, in the factory hospital, or in connection with the dozens of other organizations doing medical work, including insurance companies, benefit organizations, settlement houses, or nursing associations. All these have an opportunity which they can use if they will, if in no other way than by placing the emphasis on health. It is to my experience in a factory employing about 3,000 women that I owe my chief hope for the future of conservation, as I contrast these women with those seen in college examinations. It was not because of these ideas being impossible of realization there, that I gave up that work, but because any private business is more limited in its scope as a field for working out new plans than is an organization such as the Young Women's Christian Association to whom I am indebted for my present opportunity. I believe, however, that once it has been demonstrated as practical, the field of health education in industrial as in other fields is unlimited.

On account of the work to be done before the upward trend of civilization can be advanced as it surely will be by the conservation of the bodily health and the often interrelated integrity of mind and soul, we must go into what perhaps seems at first uninteresting and useless with the zeal typical of the medical profession, and make nothing short of health for each individual our aim.

SCIENCE TO RAISE LIFE LIMIT

In the work of the medical profession lies the best hopes of the future, states Dr. William J. Mayo, in his address on assuming the presidency of the Clinical Congress of the American College of Surgeons. He declares it to be quite possible to add fifteen years to the life of man within the next twenty years. Many of the deadly germ diseases are now under control. Typhoid, the former scourge of armies, is practically banished from them. Yellow fever and malaria go with the destruction of the mosquito. Antiseptic surgery cures the sufferer from gallstones, and the diabetic patient lives out his normal years under controlled diet.

This extension of longevity is to be looked for in a prolongation of the productive years of man; and cancer, as the chief menace of middle life and beyond, constitutes the burden of Doctor Mayo's address. Measures for the prevention and cure of cancer have not progressed along with the need. He places his usual emphasis upon chronic irritation as a predisposing factor. He considers that good dentistry has eliminated a certain percentage of cancer of the jaws, and that there is a probable relation between hot food as a chronic irritation factor in gastric cancer.

Improved technic in surgery has extended the operability of cancer to the paradoxical extent of increased experience being accompanied by higher operative mortality and a smaller percentage of cures.

He regards statistical studies in cancer, and more minute observations and reports as of the greatest importance in the estimate of the real efficacy of surgical therapy. He sees promise in the field of radio-active substances, but considers their best field in preparing an operative field against the transplantation of malignant cells during operation rather than in post-operative treatment. Immunity against cancer is sufficiently great to prevent the occurrence of cancer in some persons and to cause its abatement in others. The more highly organized glands are the more prone to develop cancer, and research in the inviting realms of bio-chemistry should be a fruitful direction for study of the causes and cure of cancer.

HANDSHAKING AS A ROUTE OF INFECTION

By H. W. HILL, M.B., M.D., D.P.H., Executive Secretary, Minnesota Public Health Association, St. Paul, Minn.

SHOULD handshaking be considered a serious route of infection?

The infective agents of most communicable diseases of the human leave the infector's body in discharges, normal and abnormal, from orifices, normal or abnormal, of the infector. They enter the infectee's body in the discharges of the infector, at orifices, normal or abnormal, of the infectee. Those pathways of these discharges, from an orifice of an infector to an orifice of an infectee, which infected discharges can follow without disaster to their contained infective agents constitute the pathways of infection. Apart from immunization the chief arts of preventive epidemiology consist in preventing the exit of living infective agents from the infector; in preventing their entrance to the infectee; in diverting or destroying them *en route*; or in a combination of any two or all three. Dealing with them *en route* is usually the most practical. The determination of these routes is therefore essential and the determination of the relative importance of the various routes is of enormous economic value. Lives, time, money have been and are now wasted without limit whenever false notions of relative importance exist, because then the measures taken are futilely directed against minor matters, the chief channels remaining as open as ever.

Remote Causes Sought

The supreme simplicity of many of the pathways followed, their utter unconcealment, has, paradoxically, left some of the most obviously direct and dangerous routes wholly undiscovered up to quite recent years. That disease is something inherently mysterious, has been an almost universal obsession of the human mind and through all man's history has led to explanations of infection the most remote conceivable,—the agency of peculiar conjunctions of the planets, the influence of malign spirits, the effects of witchcraft, the results of unusual weather and so forth,—in general of something as roundabout, as distant from the patient, and as much of a *non sequitur* as the human mind occupied at the moment with the problem could conveniently picture to itself. This mental attitude has led to a curious psychic blindness to the staringly obvious ordinary routes lying right before our eyes which we totally fail to see, the while we painfully work out obscure or intricate exceptions.

Although, as mankind has developed mentally, these beliefs concerning infection have narrowed down nearer and nearer to the patient, still they continued to be considered as something relatively abstract and remote, such as emanations from his body, clothes, etc., and it took nearly a generation to narrow from emanations to discharges, from clothes to skin. Witness the carbolic spray of Listerism, directed against the surrounding air, as contrasted with modern surgical technic, directed immediately against the surgeon and the nurse.

Attack Remoter Routes of Discharges

Even within a decade the remoter rather than the more direct routes of discharges have been the chief to be seriously appreciated and earnestly attacked. For example, in typhoid fever, the long route transfer through water was preached against years before typhoid fever was recognized as spread through the short route of direct contact.

In tuberculosis, the long route through transfer sputum thrown out upon the floor, drying and blowing about to be inhaled by passersby, was emphasized long before the short routes by mouth spray and by hands were detected. Sometimes, as in the case of sputum dried and blown about, the alleged long route danger was not an important or even a real one at all; for sputum, dried to pulverulence in nature, is dried to innocuousness, too. The real path of sputum from the ground to the infectee's mouth is through the handling of those shoes which have stepped in the sputum, provided the hands that do the handling pass to the mouth thereafter without having previously been thoroughly cleansed.

Dodges the Real Issue

This disinclination, almost inability, of the ordinary human mind to face the real issues, the tendency to see the outside of things and not the heart, is responsible for another vigorous propagandum against a long route transfer of the discharges by use of the common towel which, quite justifiable as it is, nevertheless overlooks a ten times more dangerous short route, the transfer of discharges on the hands directly by way of the handshake.

The common towel has been condemned in song and story, legislated against, driven from decent

life as an unmitigated evil, and for quite proper reasons, because hands are constantly infected with human discharges, those of the nose and mouth, the bladder, and bowels. Hence if one uses a towel in common with another, the discharges of the one may be transferred to the hands of the other through the medium of the towel; and if to the other's hands, then to his mouth, owing to the very human habit of putting the fingers to the nose, mouth, or lips at least one hundred times a day. Moreover, the common towel is often used to wipe the washed face and incidentally the lips, as well as the hands; and the next lip wiped on the same towel may well pick up the discharges left there by the previous one, thus receiving the discharges more directly. That the common towel is a route of infection there is no doubt; but, after all, the hands and lips wiped upon it have just been washed, perhaps not well, but more or less to relative cleanliness; at all events, they do not touch the towel in their original unwashed state. As compared with handshaking, the common towel is the long, uncertain, roundabout route,—the handshake is the short, direct one.

Let us confess that despite the crusades against it the common towel, if used only after thoroughly washing the face and hands, is really rather a poor method of transfer of discharges; that it is the wiping on the towel of half-washed faces and hands that constitutes the objectionable feature; and that the real danger of the common towel does not lie inherently in itself, but in deficiencies in the washing that precedes its use.

Confining ourselves to mouth discharges only, for a moment, the sequence of transfer, in the instance of the common towel, is from infector's lip to infector's hand, from infector's hand to towel, if the washing be badly done, from infected towel to infectee's hand, and from infectee's hand to infectee's mouth. In the instance of the handshake, however, we eliminate the washing, whether good or bad, and also the intermediary towel, so that the much shorter sequence of transfer runs from infector's lip to infector's hand, from infector's unwashed hand to infectee's hand, from infectee's hand to infectee's mouth. Theoretically, the point is clear enough that shaking hands, like mouth spray, is a route of infection of great importance; but in what relative proportion to other routes is it serious?

Short Routes of Infection

Certainly there are more direct ways of transfer than by the handshake. If the infectee's fingers go to the infector's mouth and then to his own; or if the infector's fingers go to his own mouth and then to the infectee's, the route is shorter. Such transfers occur constantly when children play with each other, when mother plays with babe, or when careless dentists deal with careless patients.

Even more direct is lip to lip infection as in kissing, or in the exchange of mouth spray in close face-to-face conversations. But mouth spray and kissing are limited largely to the transfer of nose and mouth discharges, while the hands convey bladder and bowel discharges, also. Nor are hand shakes limited in operation to the exchange only of the discharges of the owners of the hands; for anyone who shakes hands with a number of people, not only may transfer his discharges to all of them from his hand and receive all of theirs on his, but he may transfer the discharges of the first to the second, of the second to the third, and so on. The public character who shakes fifty to five hundred hands in rapid succession at a reception may wash his hands first and so eliminate his discharges from transfer to others; he may wash his hands afterwards and so guard himself from the fifty to five hundred risks of infection he has encountered; but he cannot well eliminate the transfer of discharges from the earlier persons whose hand he shakes to the later comers following. The more firm, cordial, and energetic the hand clasp, the more sure the transfer.

Considering the urine and the intestinal discharges, the hands have almost a monopoly of the traffic; in typhoid fever, paratyphoid fever, and dysentery, mouth spray plays little if any part; although in cholera, the vomiting of intestinal contents make the mouth discharges infective, and therefore more or less the mouth spray, also. In all the intestinal diseases other than cholera, however, the hands are the great contact factor, and the mouth discharges may be practically ignored.

Moreover, while it is true that in those diseases characterized by the presence of infection in the nose or mouth, diphtheria, scarlet fever, influenza, measles, tuberculosis, syphilis, etc., the mouth spray is important and at first sight might be considered as of greater importance than the hands; yet the crucial tests of actual practice, as in contagious hospitals, show that care as to hand infection, even though mouth spray be ignored, almost eliminates cross infection; but care of the mouth spray, if hand infection be ignored, reduces cross infection relatively little. In surgical practice, also, neglect of the mouth spray of nurses and doctors is less important than the neglect of the hands, although careful technicians will, of course, guard against both.

The general conclusion of most practical observers has been that the route of hand infection is the great pathway of infection, and is

responsible for perhaps 90 per cent of all contact infection, medical or surgical, excepting the venereal diseases.

Infection Contacts Through Handshaking

We laugh at, and secretly shudder over, the promiscuous embracing of the southern European, the promiscuous kissing of the French, the promiscuous rubbing-noses of the Eskimo. It is time that we laugh at, and shudder over our own hand shake since it is scarcely less intimate as a method of infection contact although we think of it as much less intimate from an esthetic standpoint.

The military salute is every bit as respectful, every bit as cordial, and infinitely more sanitary. "The intimate hand clasp of united souls" can very well be kept, as we keep kissing, for special occasions. Why cheapen it by the formal touching of our fore paws together at every opportunity?

At least a hundred million hands meet in hand shakes daily in the United States. The sociological pathways of infection thus provided are interestingly intricate in their possible ramifications. President Wilson "shakes" with a man from Podunk, who shakes with his Senator's secretary, who shakes with his landlord, who shakes with his doctor, who shakes with his grocer, who shakes with the commercial traveller, who shakes with the cop, who shakes with the asphalt layer, who shakes with the garbage man, all in half an hour. The reverse path of infection from garbage man to president is just as direct as in the path from president down, while the travel of infection is just as likely to be one way as the other, to say nothing of the side lines that radiate out from the direct route. Democracy is splendid, but ours should be a democracy of ideas, not of body discharges!

It will be argued that hand shakes are not dangerous because thousands are exchanged without apparent harm. True; but so, also, shells in war might be argued harmless since thousands are fired that never hit a man. Also, it is true that hundreds of thousand of acorns fail to grow into oaks; but the oaks that do grow all come from acorns; most of the men killed in battle are killed by shells; many of those who die of infection are infected through the hands.

The illogical nature of the human mind is illustrated by that habit which leads us to wear gloves as a protection against the discharges one might pick up from door knobs, "strap-hanging" in street cars, etc. This is right and proper, for the hands of others touch these things continually and leave the hand-owners' discharges on them. But custom demands further that though we may properly wear gloves to protect ourselves from these indirect and intermediary contacts with things other persons hands may have infected, we must *remove our gloves when we propose to touch those very hands themselves!*

Summary

(1) The physician or nurse who after attending a known case of infection should thereafter without washing hands shake hands with an outsider, would be committing an unpardonable breach of technic because of the risk of conveying the patient's infection to that outsider.

(2) The physician or nurse who, already sterilized for an operation, should shake hands with an outsider and proceed to the operation without re-sterilization, would be committing an unpardonable breach of technic because of the risk of conveying infection from the outsider to the patient.

(3) In ordinary life we can not know who is infected and who is not; we *do* know many are infected; is our ignorance as to just exactly who is infected a reasonable excuse for taking the chances of spreading that infection, to ourselves, our friends, and all about the community?

(4) While the hand shake does not rank with kissing in directness, it is not confined like kissing to the exchange of nasal or oral discharges, but includes the discharges of the bladder and bowel, also. Moreover, while the bulk of the discharges on the hands is usually small, the hands are so constantly infected and handshaking is so constantly repeated that, in the long run, it probably eclipses the relatively less common and less promiscuous kissing in its sum total damage.

While every medically or biologically trained person will see the force of this situation at once, the sociological difficulties in the way are very great. The general public do not recognize any danger until it has materialized in disaster. Nevertheless, a gradual training against promiscuous hand shaking is possible and cannot fail in the long run to accomplish some reduction in the transfer of disease.

(6) Certainly hand shaking should be very definitely recognized by all medical and public health teachers as one of the most important methods of personal contact leading to infection.

(7) Persons with infections, not isolated, such as persons with colds, should not shake hands; certainly not with that hand which they use for their handkerchief; in influenza epidemics, hand shaking should be abolished entirely.

(8) The natural sanitary substitute for hand shaking is the military salute.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

LABORATORY FACILITIES IN RURAL DISTRICTS

DR. HARE, addressing the medical faculty of Philadelphia in 1918 on the relations between medicine and chemistry, stated that all the necessary experiments for the application of chemical knowledge to the problems of medicine could be performed with apparatus and reagents contained in a small hand case.

At present it would be impossible to include the barest essentials of a diagnostic laboratory within the space of a good sized room. Moreover, owing to the diversity of knowledge and skill required for the various laboratory adjuncts to clinical practice and to the immense volume of the technic of the latter, it is not practicable to combine with a general practice the conduct of a diagnostic laboratory. Yet, without drawing on the resources of such a laboratory, the clinician is giving but a lame service to his patient.

In the matter of diagnostic laboratories the cities and larger towns are well provided, at least for those who can afford to pay for their services; but there are, in the United States, many rural districts entirely devoid of such facilities.

A law of the state of Ohio provides that each county shall maintain a laboratory for public health purposes. In suitable cases, with the approval of the state Board of Health, adjacent counties may combine to set up a joint laboratory, or to make arrangements with institutions to do the diagnostic public health work of the county.

The application of the Ohio law is limited to public health work but, the principle once recognized, its extension to ordinary clinical purposes would be easy and profitable. This will be more and more the case as the preventive functions of the doctor, and especially of the family physician, increase in importance and receive recognition as cardinal factors in maintaining the public health.

A survey of diagnostic facilities should be undertaken in each state, in order to establish the existence and the extent of the need for public diagnostic laboratories, and for legislation along the lines of the Ohio law. This is advised, not because there can be any doubt as to the need, but as a means of convincing public opinion. It is rarely possible and never advisable to legislate ahead of public opinion.

THE CENTRALIZATION OF FEDERAL HEALTH ACTIVITIES

SPURRED on by the example of both England and Canada in establishing a Ministry of Health, leading health workers in this country are lending their support to the passage of a concurrent resolution providing for a congressional investigation of all Federal health agencies.

This is the first step to secure the enactment of legislation which will bring about the formation of a Federal Department of Health. The need for the coordination and enlargement of Federal health activities was very forcefully pointed out by Dr. W. S. Rankin[1] in an address at the recent meeting of the American Public Health Association. "The present form of Federal health administration is both a grievous hindrance to efficiency in national health work and a positive danger to state health work," says Doctor Rankin.

The solution to the problem seems to be the consolidation of all agencies engaged in Federal health administration in one bureau or department. The organization should be sufficiently elastic to permit extensions and additions to functions as natural opportunities and resources permit.

SUPERVISION OF INSTITUTIONS BY THE HEALTH DEPARTMENT OF NEW YORK CITY

By FRANK J. MONAGHAN, M.D., Deputy Commissioner of Health, New York City*

THIS is the day of institutions, institutions of all kinds and character. To-day, through the instrumentality of kindly philanthrophists, or through the wisdom of those who guide us in the affairs of the state or city, the institutions of which we, in the Department of Health, must take particular notice, have come strongly to the front. This is to be seen in the fact that while in 1916 there were 667 institutions in which the Department of Health was interested, in 1919 we have 1,045, of which 995 are within the city and 50 outside. This remarkable increase shows the tendency of the times. This increase is due, in my opinion, to the fact that ideas and knowledge of hygiene and sanitation are becoming more widespread. It is, in fact, a part of what has been aptly called the modern health crusade.

The Attitude of the Public

The day when an institution was looked upon as a thing of horror, to be avoided, has passed away; and to-day with the constant reiteration of matters of hygiene and sanitation, with the education of the people themselves along these lines, we find that these institutions are no longer considered places of last resort only, but that now they are even sought after by those who only a few years ago would have rejected them with fear and trembling. To-day it is not the poor alone who seek the care of institutions, but those who have ample means, whose home surroundings are probably of the best, are recognizing the changed condition. These also avail themselves of the opportunities held out to them. Also the new ideas in medicine, the so-called "group system" which is the latest advance, undoubtedly will result in a larger number of institutions of this character coming under the direction of the Department of Health of the City of New York.

This somewhat changed condition and the growing number of institutions, make it incumbent upon the Department of Health of the City of New York to maintain a strict and farseeing supervision of these institutions. This is a particular and well recognized function of this Department and, in the words of one of our contemporaneous writers, "this is one of the things that we do well."

*Read before the New York State Conference of Charities and Corrections, Syracuse, N. Y., November 13, 1919.

For the purposes of supervising institutions, the Department of Health of the City of New York has instituted the Division of Institutional Inspection. Prior to the time this Division was organized, matters connected with institutions were supervised by three different divisions, which made for confusion, needless duplication, and lack of initiative. To-day this Division, composed of a chief and twenty-one inspectors, is directly connected with the office of, and reports to, the Deputy Commissioner of Health.

Two Groups of Inspectors

These inspectors are divided into two groups, twelve inspectors doing work in all institutions, and nine making physical examinations of children in institutions subsidized by the city,—that is, institutions receiving pay for the board and care of children. The city is divided into approximately uniform districts and the first group of inspectors are subject to call daily from 9 a. m. to 5 p. m. in their own districts, and each in turn covers the diagnosis work of the whole borough to which he is assigned between 5 p. m. and 9 a. m.

Group 2, except when called upon to do emergency work, does all its work in institutions subsidized by the city. Inspectors make physical examinations in institutions assigned to them and make routine sanitary inspections of these institutions. Two inspectors are assigned to out-of-town work, and do exactly the same work as those in Group 2.

The Division now has under its supervision the following:

	In town	Out of town
Hospitals	133	..
Dispensaries	111	..
Diagnostic laboratories	169	..
Private sanitariums	71	..
Homes for adults	174	..
Homes for children	127	49
Day Nurseries	115	..
Homes for the aged	52	..
Homes for incurables	17	..
Reformatories and prisons	25	1
Miscellaneous	1	..
	995	50

The functions of this division include: (1) diagnosis in institutions; (2) sanitary inspections in institutions; (3) special examinations, administration of sera, etc.; and (4) physical examinations in institutions.

Functions of the Inspection

The first and foremost function, diagnosis in institutions, which is ever immediately urgent in character, is performed in all of the institutions

except those outside of New York City. The necessity of accurate and rapid diagnosis, the securing of proper isolation and quarantine, the removal of certain cases to appropriate city hospitals, the proper discharge from quarantine of cases of communicable diseases, and the investigation of cases of abortion and puerperal sepsis, is recognized by everyone.

Sanitary Surveys Important

The second function, which is an important one and which is also performed regularly in all of these institutions within as well as without the city limits, is that of sanitary inspection. The following guide devised by the Chief of the Division of Institutional Inspection is followed by the medical inspectors in conducting their sanitary investigations. It will be seen that sanitary surveys made under this guide are most comprehensive and elaborate, and that it has been of the utmost value as a matter of record.

Name of Institution.

Address of Institution.

Character.

Grounds.—A short description of the grounds as regards extent and character of the surface (grass, dirt, cement), its drainage; general cleanliness.

Buildings.—Location as to grounds; character of construction of the building or buildings; and general condition from outside appearances.

Fire Prevention.—Fire escape, chemical fire extinguishers; fire pails (whether containing sand or water); fire alarm system; water hydrants outside of buildings to be used for fire hose connection; fire drills.

Plumbing.—Nature and adequacy of the plumbing.—it must be open; the number of baths, both tub and shower, as compared with the number of inmates who are designated to use them; the number of toilets, with their location, and the proportion of toilets to the number of inmates who are required to use them. Washrooms, bathrooms, and toilet rooms must have impervious floors, with no leaks.

Ventilation.—Nature and adequacy; natural or artificial.

Heat.—Character and sufficiency of (a) steam;

Average time for 1 inspector for 1 day

hours minutes

Chief, Division of Institution Inspection

Fig. 1. Chart used for analyzing physical examinations. The original is 13½ by 14⅜ inches and has space for reports of the primary examinations and also for re-examinations.

(b) hot air; (c) hot water; (d) gas stoves; and (e) coal stoves.

Light.—Nature and adequacy; natural or artificial; (a) gas; (b) electricity; (c) lamps; or (d) candles.

Adequacy of Equipment

Dormitories.—Location and general description, giving the number of cubic feet of air space in each, the number of beds, and whether two feet apart or not. Six hundred cubic feet of air space to be allowed for each bed, as required by Section 313 of the Public Health Law. If a less number of cubic feet of air space is allowed, the reason for such must be given, as for example, exceptional ventilation.

Beds.—Character of the beds—whether metal or wood; whether single or otherwise, and whether more than one occupant. Springs, whether ordinary or woven. Mattresses, whether hair, felt, or straw; whether protected by rubber sheeting.

Bed Clothing.—Character and frequency of change; adequacy and seasonability; nature of night clothing of inmates.

Sitting Rooms.—Furnishings and conveniences.

Dining Rooms.—Proper light and ventilation; cleanliness. Are the rooms screened? Character of the seats. Have the chairs or benches backs upon them? The character of the dishes,—whether crockery, enameled iron, etc. Have the tables table-cloths? If so, how often are they changed? Are individual napkins used? If so, how often are they changed? Are the dishes and eating utensils clean? Are individual drinking cups or glasses provided? Are food handlers provided with food handlers' certificates?

The Kitchen Equipment

Kitchen.—Is it fully and properly equipped? Are tables zinc covered? Are they in good repair?

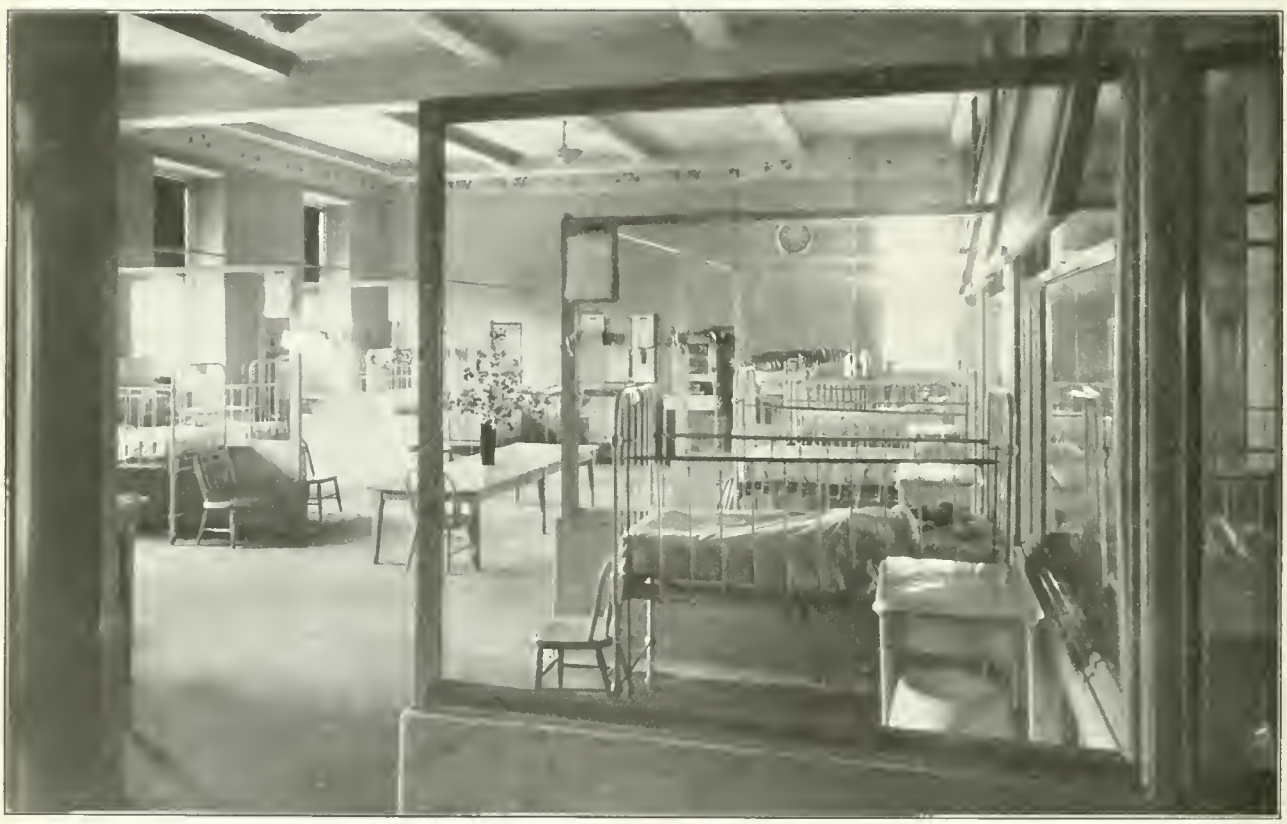

Fig. 2. There is no lack of comfort or amusement for these "kiddies" e en though they are inmates of an institution. One function of the Department of Health in New York is to see that all child caring institutions are kept up to a high standard of efficiency.

Are the utensils clean; if copper or brass, are they thoroughly clean and free from verdigris? Is a common roller towel in use? Is the room properly screened in warm weather? Are fresh vegetables used when procurable? What is the general character of the food as to its quality?

The Handling of Supplies

Refrigeration.—Is the refrigerating plant of proper size? What is the character of the refrigeration? Are separate compartments provided in refrigerators for (1) milk, butter, and eggs; (2) meats; and (3) fresh vegetables?

What grade, or grades of milk are used? Is the milk for drinking Grade A or B? Is Grade C milk used for cooking?

Garbage.—How is the garbage disposed of? Are garbage cans properly covered? Is an effort made to prevent the breeding of flies in and about the kitchen and grounds?

Storeroom.—General description.

Drinking water.—Nature of; how furnished, by drinking fountains or taps with cups? Are individual cups or glasses furnished? Is the water wholesome?

Classrooms.—Kind of light, heat, and ventilation. The relationship of the light to the desks and to the blackboards; general cleanliness of the rooms.

Playrooms.—Conditions as to light, heat, ventilation, cleanliness, water supply, and toilet and washing facilities.

Children.—Their clothing. Is the clothing seasonable and of proper amount? The cleanliness of their bodies.

Bathing.—How often bathed and how? Shower or tubs? Is more than one child bathed in the same tub of water without water being changed? Are individual towels, wash rags, tooth brushes, tooth powder, combs, soap, and sponges provided? What method is used to preserve their individuality? Are fine combs disinfected after use? Are the boys allowed to use hair brushes? Is liquid soap used? Is any effort made to teach oral hygiene?

Matters of General Sanitation

General.—Is the institution supplied with a permit? This is necessary where the inmates are sixteen years or under. Are dormitory placards posted in each and every dormitory, and is the permit exceeded.

Inmates.—Between what ages?

Census.—Male and female.

Fig. 3. Fragrant blossoms give this ward a cheerful "homey" atmosphere, and the chairs were especially designed to fit the small occupants.

Attending physicians.—Does the name of the attending physician appear in a conspicuous place in the hall?

Cleaning and sweeping.—How often is this done? No dry sweeping is permitted.

Hospital facilities.—Hospital,—how many beds? Infirmary,—how many beds? Quarantine room or rooms,—how many beds? Isolation room or rooms,—how many beds? Physicians and other attendants,—how often do they visit the institution? Nurses, hospital equipment, and drugs: Is the medicine closet kept locked when not in use? Are records kept of everything done in the

hospital and dispensary? What is the nature of the records kept?

Sample menus.

Sewage.—Does it empty into the river? Is the sewer connected with cesspool or disposal system? Condition of roof and rain leaders? Is there a stable on the premises? Possible sources of nuisance in the vicinity,—smoke, offensive trades, stagnant or undrained areas?

Laundry.—How is machinery run? Equipment. Engine room. Boilers,—high or low pressure.

Staff.—Educational; help.

Recreation.—Where and how much?

Sleep.—Hours of going to bed and arising?

Recommendations.

Statement of authorities.

A third function is also performed in all institutions, no matter what the type: namely, the administration of sera, and vaccines; the application of the Schick test; the collection of cultures, smears, and blood for laboratory examination; the medical examination of food handlers in institutions and the performance of field work for the Divisions of Epidemiology, Venereal Diseases, Tuberculosis, Industrial Hygiene, Midwives and Foundlings in so far as their work affects

DEPARTMENT OF HEALTH—CITY OF NEW YORK BUREAU OF GENERAL ADM DIVISION OF INSTITUTIONAL INSPECTION

25 1M3 18-R Form 22 B

Fig. 5. Blank used in reporting physical examinations and numerous re-examinations. The reverse side, Figure 6, gives the average height in inches and weight in pounds of boys and girls.

Re-examinations of those found with defects in order to determine whether or not defective conditions have been remedied are performed each year in May and June, and again in November and December.

We may now consider the detailed supervision exercised in the various types of institutions:

The Supervision of Hospitals

The extent of hospital supervision by the local Department of Health depends upon the organization of the institution. Hospitals organized under the membership corporation laws, being philanthropic in purpose, are under the direct jurisdiction of the State Board of Charities so far as their organized maintenance and conduct are concerned. We do, however, perform regular sanitary inspections and, on call, representatives of the Health Department respond for purposes of diagnosis of communicable diseases; for the enforcement of isolation and quarantine; the removal of appropriate contagious and infectious cases to special hospitals, and for the proper discharge of all patients with communicable diseases.

Hospitals organized under the business corporation laws, so-called private hospitals, are entirely under the jurisdiction of the Health Department and the complete procedure in these cases is as follows:

First, approval of site must be obtained from the Board of Health. In making application the following points are considered by the Board: (1) the necessity for the hospital in the particular locality under consideration; (2) the character of the work to be performed. If maternity cases are accepted, this must be specially mentioned; (3) the financial responsibility of the owners and their capabilities for efficient management; (4) the names and addresses of those who will perform work at the institution; and (5) it is desirable also to detail the fact that there will be no objections on the part of neighboring property owners and residents.

If the Board of Health gives its approval of site, the next step in procedure is to obtain from the Bureau of Buildings, a certificate of occupancy for hospital purposes. Next, we must be in possession of a certificate from the Bureau of Fire

REMARKS

Fig. 6. Reverse side of the blank used in reporting physical examinations, with tabulations of average height and weight and space for making records. The front of the card is illustrated in Figure 5.

Prevention of the Fire Department stating that there are no violations, so far as this city department is concerned, pending against the premises. In the interim, an application filled out on an official blank must be presented.

The supervision of private sanatoriums involves the same procedure as with hospitals organized under the business corporation laws.

Finally, when these requirements have been satisfactorily met, a complete sanitary survey of the premises is made by a duly accredited representative of the Division of Institutional Inspection and, if his report is favorable, a recommendation is made that a permit be granted.

With this type of hospital, the routine work is the same as with the first mentioned class, namely, the regular sanitary inspection of the building or buildings, and the diagnosis, sanitary control, and proper discharge of all communicable disease cases. The sanitary inspections the same as in other hospitals. Diagnosis is made and removal ordered to appropriate hospitals of cases of communicable disease.

Every laboratory in New York City offering facilities for the diagnosis of communicable diseases must be in possession of a permit issued therefor by the Board of Health. On the receipt of an official application for such a permit, a medical inspector is detailed to examine: (1) The equipment, minimum requirements for which have been determined upon, to see that the laboratory is possessed of facilities to make diagnosis of disease and conditions specified in the application, and for (2) regular and systematic sanitary investigations. Where these homes receive city money, the inmates are regularly given physical examinations and those with physical defects re-examined. Sanitary surveys are also performed. If they receive no city support, no physical examinations are ordinarily conducted.

Perhaps nowhere in the world are homes for children, the so-called child caring institutions, so carefully and conscientiously supervised as they are in New York City. The safeguards placed about children in these homes by the Health Department are

most comprehensive, and it devolves upon the Division of Institutional Inspection not only to carry out the policy of the various city departments, particularly that of the Department of Health, but from time to time to inaugurate progressive measures, looking to the further betterment of the lives of the inmates. Constructive criticism is indulged in by duly authorized medical inspectors on the occasion of their many visits for the purpose of performing their routine duties.

The Sanitary Code reads as follows: "Board and care of children regulated. No person other than a superintendent of the poor, a superintendent of almshouses, or an institution duly incorporated for the purpose, shall receive, board, or keep, except under legal commitment, any nursing child, or any child under the age of twelve years who is not a relative, pupil, or ward, or an apprentice of such person, without a permit therefor issued by the Board of Health or otherwise than in accordance with the terms of said permit and with the regulations of said Board (S. C. 197)."

Institutions of this character incorporated for the purpose or maintained for the care of children under legal commitment, need no permit from the Health Department except where less than 600 cubic feet of air space per child is allowed. Under these circumstances, the State Board of Charities authorizes the local Board of Health, in view of unusual ventilation, to issue permits for dormitories in which there are less than 600 cubic feet of air space per child. Section 482, Penal Law, State of New York, provides that a person who (1) wilfully omits without lawful excuse to perform a duty by law imposed upon him to furnish food, clothing, shelter, or medical attendance to a minor, or to make such payment toward its maintenance as may have been required by the order of a court or magistrate when such minor has been committed to an institution; or (2) not being a superintendent of the poor, or a superintendent of almshouses, or an institution duly incorporated for the purpose, without having first obtained a license in writing so to do from the board of health of the city or town wherein such females or children are received, boarded, or kept, erects, conducts, establishes, or maintains any maternity hospital, lying-in asylum where females may be received, cared for, or treated during pregnancy, or during or after delivery; or receives, boards, or keeps any nursing children, or any children under the age of twelve years not his relatives, apprentices, pupils, or wards without legal commitment, is guilty of a misdemeanor.

Prior to the issuance of such permit, we insist upon the possession of a certificate of occupancy from the Bureau of Buildings and a certificate from the Bureau of Fire Prevention of the Fire Department to the effect that there are no violations, in so far as this latter Department is concerned, pending against the premises and that the building or buildings are suitable and safe for the purposes to which it or they are to be put.

Applications for these permits are made on official blanks furnished gratuitously by the Department.

Day Nurseries

The Sanitary Code defines a day nursery as a place where more than three children are received, kept, and cared for during the day time. We have under our jurisdiction at the present time, 115 day nurseries.

In order to conduct a day nursery, it is required that a certificate of occupancy be obtained from the Bureau of Buildings and a certificate be obtained from the Bureau of Fire Prevention stating that there are no violations pending against the premises.

DEPARTMENT OF HEALTH—CITY OF NEW YORK
MEDICAL INSPECTOR'S DAILY REPORT
25-1094-18-B, Form 130 K

BUREAU OF CHILD HYGIENE
DIV OF INSTITUTIONS AND CHILD CARING AGENCIES

Fig. 9. The medical inspector makes a daily report of re-examinations on the above card.

An application must be completed and signed by the persons proposing to conduct a day nursery and a sanitary inspection must be made by one of the inspectors of the Division of Institutional Inspection. This report includes the measurement of the rooms. The Sanitary Code provides for a minimum of 200 cubic feet of air space for each child. These reports being favorable, the papers governing the case are forwarded to the Board of Health with a recommendation that a permit be granted. The permit states the maximum number of children allowed.

Monthly Inspections at Nurseries

A routine sanitary inspection is made of all the day nurseries at least once a month. Inspectors at this time report on the sanitary conditions found and also on the conduct of the nursery by

67 K—1913 22 .75, '18, 600 (F)

To the Board of Health of the Department of Health of The City of New York:

The undersigned hereby applies for a permit to keep beds in dormitories, in situated at

Signed,

I visited and examined the above-mentioned premises, and have found the conditions to be as follows:

ROOMS		SIZE OF ROOMS				VENTILATION			NUMBER OF BEDS ALLOWED
Floor	Room No.	Length	Width	Height	Cubic Feet	No. of Windows	Location of Windows	Other Means	

M. D.
Medical Inspector.

Dated, , 191

Fig. 10. Form which must be filled out before permission will be granted to open a child-caring institution. The medical inspector's report of conditions in the premises described must also be included.

the day nursery's own physician and the matron of the institution. The records of the day nursery must show that child was inspected on admission and thereafter twice a month by the physician attached to the nursery, the examinations to be at least two weeks apart.

In case any contagious disease is found the child must be put into the isolation room, as is required, and the Department of Health must be notified at once.

Standards of Nursery Hygiene

Rooms of all day nurseries must be above the street level unless there is a cellar underneath the room so occupied. Provisions are made regulating the cleanliness, ventilation, light, heat, and care of food, including care of bottles and nipples used, outer garments, and arrangement of the beds or cribs so that there shall be a space of two feet, except where the head or sides of the crib may touch the wall; the use of wire springs, the use of blankets over the springs instead of mattresses for the sake of cleanliness. The use of common wash cloths, towels, combs, or brushes is prohibited. Special attention is paid to the care of diapers, and the nursery is required under certain conditions to provide over-aprons.

The matron is required to inquire daily of the mother or other person bringing the child as to whether or not any sickness exists in the child's home and if any suspicion is aroused as to the possibility of such sickness being of an infectious

nature, the child is excluded from the day nursery, the Health Department notified and the exclusion continues until a certificate of the Department of Health is furnished to the nursery to the effect that the premises referred to are free from infectious disease.

Homes for the Aged

There are fifty-two homes for the aged under supervision. The procedure is the same as in the case of homes for adults.

We have under us seventeen homes for incurables. The procedure followed is for the most part the same as in other homes for children, as the majority of these homes are for children. Where the inmates of the institutions are adults, the procedure is the same as in other homes for adults.

Of reformatories and prisons there are twenty-five in town and one out of town. By arrangement with the Commissioner of Corrections, the Division of Institutional Inspection of the Health Department makes regular routine sanitary inspections at these institutions. They include not only reformatories and prisons of all sizes, but also the local minor places of detention attached to the various district police courts. The institutions of this type which house their prisoners for periods of some length, as a routine procedure, have their inmates regularly examined physically, by our inspectors.

It will be seen by the foregoing how extremely important this work is considered by this Depart-

ment. Nothing in its inspection is considered too small to overlook, and the inspectors in making their visits to these various institutions are not only supposed to consider the exact rules and regulations laid down by the Department for their guidance, but exercise good judgment from the knowledge that they have acquired in the routine

of their daily practice from the observation of other institutions, and even suggest ways, means, and changes that add exceedingly to the value of the work that these institutions are called upon to perform.

During the existence of epidemics, such as influenza, the supervision of all institutions, especially those of child caring institutions, has taught a lesson of great value. It was interesting to note during the recent great epidemic that in those institutions from which the public were excluded rigorously the epidemic gained little foothold and its ravages were comparatively light. This was gratifying, and it was also noted in marked contrast with this, that those in households, where every care could be given, often seemed especially subject to this disease.

This was also observed during the epidemic of poliomyelitis. It proves that if an efficient quarantine could be instituted and maintained all infectious disease would be excluded, the lives of the inmates safeguarded, and it would materially assist in stamping out these scourges.

In regard to institutions devoted to child-caring, we find our greatest contentment in knowing the remarkably good results that are achieved by following out the wise regulations of this Department and of allied departments of the state and city. It is now well recognized, and this is as it should be, that all the care that can be given to these little dependents is worthy of our utmost consideration, and it is a pleasure to note the fact that money expended in the welfare of these little ones is, at the present time, not begrudged by any one. All officials of the state and city recognize that money so spent is well spent.

To observe the well ordered and well conducted child caring institution with its up to date fixtures and appurtenances makes one feel that at least we recognize the value of these future citizens of our state and city, and that time and thought spent in this connection could not be spent in a better cause.

The Department of Health of the City of New York has given much time and attention to the supervision of all institutions, but particularly to the child caring institutions in which it recognizes the value of frequent and painstaking inspection.

The Division of Institutional Inspection, with its well trained staff, is always on the alert for anything that will increase the value of these institutions, and is ready and willing on all occasions to impart its knowledge for the betterment of existing conditions.

It is believed that the officials of the city of New York, well recognizing the fact that these institutions are worthy of all the care that can be given to them, will, in the future as they have in the past, continue to supervise with an anxious eye all the institutions under their care, and that those in power in the city administration will not be niggardly in their appropriations for the furthering of one of the most important activities of the Department of Health, and therefore will not stint us when the appropriations are made covering this work, which is of such great magnitude.

LAW FOR THE DOCTOR

By LESLIE CHILDS, Attorney-at-Law, Indianapolis, Ind.*

Right of Physician Selling Location and Practice To Resume Practice in Immediate Vicinity

To the professional man buying an established location and practice, the question of just what he is buying is of great importance. It is frequently the case that the intangible part of the property, usually designated as "good will," is of far greater value than the land, shop, stock in trade, or what not that is purchased. This being the case, it is of great interest to know just what amounts to a sale of the "good will" of a professional practice.

If in the contract of sale there appears a specific stipulation that forbids the seller again to engage in the practice at or near the location sold, that of course is binding. Or if there is a stipulation reciting that the "good will," of the practice is parted with, that, too, in law will prohibit the seller from again engaging in the practice at the former location, within reasonable restrictions.

But suppose that neither of the above stipulations is set out in the contract, and the seller after a time resumes his practice, to the detriment of the buyer, has the latter any remedy, and if so what? The answer is that whether or not the buyer has any recourse will depend almost entirely upon the nature of the representations made by the seller at the time of the sale. The case of Townsend *vs.* Hurst, 37 Miss. 679, is one directly in point, illustrating the application of the law on this proposition in an admirable manner, the facts being substantially as follows:

The defendant advertised his place for sale, offering to sell his land, dwelling, shop, and stock of medicines. He represented it as a good location for a physician. He stated that his reason for wishing to sell was that he was in bad health and intended to remove to Florida. He also stated that he knew his land was not worth much, but that it was for his stand as a physician and for his improvements that he asked the price. He further promised to recommend the plaintiff to his patrons.

Upon the above representations the plaintiff, a young physician, purchased the land, dwelling, stock of medicines, etc., paying one-half the purchase price when it became due, and giving his note for the balance.

After the sale the defendant removed to Florida, but returned in a few months and resumed the practice of his profession within one mile and a half of his former stand. Whereupon the plaintiff refused to pay the balance of the purchase price, filing a bill to enjoin the collection of the same, and asking for a recision of the contract on the grounds of fraud, misrepresentation, and a failure of the defendant to live up to the contract.

*The ninth of a series of articles on "Law for the Doctor" written for MODERN MEDICINE by Leslie Childs.

It should be remembered that there was no stipulation in the contract of sale forbidding the defendant again to resume the practice of medicine at or near his former stand. Neither was there any express stipulation that there had been a sale of the "good will" of the practice. In passing upon this set of facts the court said:

"Good faith and justice require that parties making representations and holding out inducements intended to influence the action of those with whom they deal in matters of contract, and upon which they are expected to rely and do rely, should be strictly held to make good such representations, and to fulfill the reasonable expectations thereby created. It is of the last importance that courts of equity should rigidly adhere to a rule so consonant with morality and common honesty. . . . The question is, did not these representations and this conduct on the part of the defendant, naturally and necessarily lead appellant (plaintiff) to believe and understand that defendant would at least not continue the practice of medicine in that immediate vicinity? Did he not understand from the representations and promises made to him that he was to have the defendant's stand and his "good will," as the main inducement to the purchase?

"The testimony leaves no doubt on this point. Was the appellant (plaintiff) deprived of the benefit he had the right to expect by the act of the defendant? This seems equally clear from the testimony. According to some authorities, by the conveyance of a shop alone, the good will passes, though not specifically named. . . . But in this case it was expressly sold as a stand for a physician, with the statement that defendant intended to remove to Florida, and with the promise to recommend appellant (plaintiff) to his patrons.

"Under such circumstances, the conduct of the defendant in returning and resuming his practice among his old patrons was such a violation of good faith, and such a fraud on appellant (plaintiff) as entitles him to the relief he seeks."

By this opinion the court in effect held that there was an implied covenant that the seller would not re-engage in the practice at his former location; and that as he did this he could not enforce the payment of the balance due on the sale, the contract of sale being rescinded.

In conclusion then it may be stated. That if the contract of sale expressly prohibits the seller from re-engaging in the practice at a given locality, for a given time, it is binding. Or if the contract expressly specifies that the sale is one in which the "good will," is transferred, this will also prevent the seller from re-engaging in the practice in a manner that would interfere with the buyer.

On the other hand if the transfer is a straight sale, whether or not the seller will be prevented from re-engaging in the practice at his former stand will depend almost entirely upon the representations and promises made and relied upon by the buyer at the time of sale. And the case reviewed above is an excellent example of representations and promises that will in themselves constitute a sale of the "good will," and thereby serve as a bar to the seller from re-engaging in the practice to the damage of the buyer.

TUSKEGEE NEGRO CONFERENCE

The Twenty-Ninth Tuskegee Negro Conference will be held on January 21 and 22 with the general subject of discussions to be "Meeting the Needs of the New Economic Conditions." The ultimate object of these conferences is to contribute something toward the fullest development of the South along all lines.

ILLNESS CHIEF CAUSE OF POVERTY

That at least half the cases of poverty are due to illness was demonstrated by the Brooklyn Bureau of Charities which made a survey during the past year. With only a narrow margin of savings, the family is quickly reduced to destitution by illness.

Y. W. C. A. HEALTH CONFERENCE

A conference of the women physicians actively engaged in work at the health centers of the Young Women's Christian Association convened in New York December 1 to 6, 1919. The "Evolution of the Health Center" was presented by Dr. Florence Meredith. Dr. Augusta Rucker, director of the health division of the Bureau of Social Education, spoke on "Health and the Modern Woman." Many such health topics as exercise and heart murmurs, individual health exercises, and topics on matters of administration and the relation of the physician to the physical director were discussed. Miss Hazel MacKaye spoke on the psychology of recreation, and "Mental Health" was presented by Dr. Eleanor Bertine. The subject material is sufficient indication of the constructive tendency of the health program which has ben outlined for the health centers of the Young Women's Christian Association.

HOSPITAL SOCIAL SERVICE QUARTERLY

In an article entitled "Medical Social Service of the Future," published in the November issue of the *Hospital Social Service Quarterly*, Dr. Charles P. Emerson quotes Sir William Osler, commenting on the patients collected in a medical dispensary, as saying: "If three out of ten of these get what they really need, we are doing well. We are not equipped to treat the other seven." To help the other seven, says Doctor Emerson, is a medico-sociological problem, and if he wishes to succeed, the doctor must associate himself with an expert in that field." He decries the use of the term "social service" in this connection, and says it would more accurately be termed "community medicine," for its chief concern is the community aspects of disease. His vision of medical social service of the future is: (1) Better therapy through partnership with expert sociology. (2) The education in the laboratory of human life of sociologists, of medical students, of nurses, of charity workers, and of patients that they may more intelligently cooperate with their doctors. (3) The provision of ways and means by which the medical service of a hospital and dispensary may be made more satisfactory to the patient, the doctor, and to the public in every possible way.

John E. Ransom contributes to the same issue a well written article on the training for hospital social service through the development of hospital community relationships.

Other articles are presented as follows: "Medical Social Diagnosis," by Imogene Poole; "Readjustments Which Training Schools are Facing," by Laura R. Logan; "Social Service Work for Syphilitic Persons," by Albert Keidel, M.D.; "The Volunteer Worker," by Charlotte F. Rosenbaum; "The Value of Occupational Therapy in the Nurse's Profession," by Charlotte Moodie, R.N.; "Social Service at the Italian Hospital," by Mrs. Lionello Perara; "The Midwife in the City," by Etelka Weiss; "Course of Instruction for Dietitians," by Katherine Fisher; "American Conference on Hospital Service," by M. A. Cannon; and "Social Service at the Illinois Training School for Nurses," by N. F. Cummings.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

THE CONTROL OF HUNGER IN HEALTH AND IN DISEASE. By Anton Julius Carlson.*

Carlson has written in this book, the results of a long series of researches by himself and associates, which have extended over a long period of time and have appeared in many numbers of the *American Journal of Physiology.*

It is recommended that those who have not the original articles available should by all means read this book, as in the book there is not only a complete review of all previous work on the physiology of gastric motility and digestion, but also a fund of new information contributed by Carlson, which constitutes the most important advance in our knowledge of gastric physiology up to the present time.

The book is written in a clear, simple, vigorous style, is well arranged, and quite well illustrated. There is also appended a very complete bibliography.

The opening chapter deals with the biological significance of hunger, and contains a discussion, quite philosophical in its nature, of hunger in unicellular animals, plants, higher animals, and also the interrelationship of hunger and appetite. This interesting chapter and the one which follows, which is devoted entirely to the theories of hunger and appetite, indicate the author's remarkable familiarity with the entire subject of the physiology of the gastro-intestinal tract. One notes with pleasure in these chapters, and also throughout the entire book, Carlson's scientific honesty, especially in his carefulness to attribute previous investigations to the individuals responsible for the work. He states simply and directly that his work began where the work of others left off. He claims no originality for his main method of investigation, but attributes it properly to Boldyreff, Cannon, and Washburn.

After Carlson's work was well started he was fortunate, as he states, in securing the services of "a second Alexis St. Martin,—a man with complete closure of the esophagus and a permanent gastric fistula of twenty years' standing." The gastric fistula was large enough to permit direct inspection of the interior of the stomach and the introduction of *ballons*, etc., for various investigations. The method of investigation most used was that of introducing into the stomach a thin-walled rubber *ballon* attached to a rubber tube, and this connected with a bromoform recording manometer. When the *ballon* is distended with air to the proper degree, contractions of the stomach are recorded through the manometer on a smoked drum. In the man with the gastric fistula, the *ballon* was introduced through the fistula. In normal individuals and patients, the *ballon* is attached to a small rubber tube and swallowed, in the same way that a Rehfuss tube is swallowed. Another method used was x-ray examinations of a bismuth coated *ballon* introduced into the stomach, thereby pictorially recording gastric motility.

The most important contribution of Carlson was definitely to prove the fact that the empty stomach is not at rest, but has a certain degree of tonic contraction which is rythmic in type. The previous work of Boldyreff and Cannon did not demonstrate this.

The author also confirmed and elaborated the observations of these last named investigators, that, when hunger occurs, there also occur strong intermittent contractions of the stomach, and that these contractions are absolutely coincident with the pangs of so-called pains of hunger. Probably the most important information for the clinician is the fact that there is a relationship between the tonic contractions of the stomach and other conditions which may affect either the stomach or the individual's general condition. Work along this line is already appearing in the current literature and it is hoped that many clinicians will see the value of Carlson's methods in studying patients with gastric disease, both before and after operation.

Carlson has confined himself practically entirely to the physiology of hunger and gastric tonicity. The field made up of pathological conditions of the stomach is still almost untouched and undoubtedly much can be learned here by these newer methods.

Especially important chapters in the book are: Sensibility of the gastric mucosa.—The nervous control of the hunger mechanism.—The chemical control of the hunger mechanism.—The characteristics of human appetite, gastric juices.—Hunger and appetite in disease.

The work which this book represents is a masterpiece of thorough, complete, scientific investigation of a more or less abstract problem. It is noteworthy, however, that one can read between the lines the realization which the author has of the important practical application of his investigations.

*University of Chicago Press, Chicago, 1916. $2.

A SERIES OF CONSECUTIVE CLINICAL DEMONSTRATIONS AND LECTURES. By Frank Smithies, M.D., Augustana Hospital, Chicago.*

This new periodical, as is indicated by its subtitle, presents a series of consecutive clinical demonstrations and lectures. The clinical demonstrations—in this issue thirteen in number—cover many aspects of the internist's field; the lectures, as, for example, those appended to the clinics on gastric syphilis, and on ulcerative enterocolitis, are based upon work which Doctor Smithies has published elsewhere. The appended descriptions of the laboratory tests used in the development of the particular case represent another feature of these clinical lectures.

"A Separate Bed for Each Sleeper"—Another Sensible New Year's Resolution

The reasons for changing one's habits of sleep, are as simple as they are sound. If there were no specific sanitary reasons for Metal Beds and a separate bed for each sleeper—Why do hospitals insist upon both?

There are plenty of reasons why people in ordinary health should insist upon sleeping in separate beds—epidemics, sickness, and communicable diseases only emphasize some of them.

The germs of pneumonia, diphtheria, spinal meningitis and influenza revel in close, stuffy, overheated sleeping rooms, and the old-fashioned double bed helps them in their deadly work.

During the "Flu" epidemic of 1918 nearly every newspaper cautioned against the danger of crowds. Theatres, churches, and schools were closed. Street cars and other public conveyances were operated, but their doors and windows were kept open. The big idea was to impress people with the necessity of dressing warmly, of avoiding crowds, and breathing pure, fresh air. It remained for the Army and Navy health officials, however, to stipulate how the men in their care should sleep.

Among the good health rules formulated at that time was the rule to avoid crowding. Men were urged to keep to themselves, or far enough from others so as to permit a free circulation of air.

In barracks, cantonments and transports—where crowding was almost unavoidable—it was an iron-clad rule that every soldier and sailor sleep alone, in a bed of his own. And to prevent germs from carrying from man to man, the beds or cots were arranged foot to foot, instead of in rows, head to head.

Public health officials and welfare workers are familiar with these facts. We refer to them again and again because we believe too much stress cannot be laid upon the efficiency and good-health value and importance of sound, restful sleep, and the vital part it plays in maintaining the health and efficiency of industrial workers.

Pure air in sleeping rooms is as necessary to personal efficiency as sleep, and if that sleep can be had in a modern, sanitary and noiseless Simmons Bed, so much the better.

Simmons Steel Bed equipment is the choice of up-to-date Hotels, Hospitals, Schools and Industrial Dormitories just as it is the choice of thousands of homes. Catalogs, Style Book, or helpful data on the all-important subject of sleep, will be mailed promptly upon request. Address:

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 88)

The general plan of presentation is more or less uniform in the several clinics, consisting of a well developed history, the findings on physical examination and in the laboratory, a summary (1) of the clinical history, (2) of the clinical examination, and (3) of the clinical laboratory examinations, a discussion of the diagnostic data, and of the treatment and the results of treatment. Also, as already noted, several of the clinics are followed by a thorough handling of their outstanding features (e. g. benign pyloric stenosis, and medical treatment of gastric ulcer).

Among the conditions thus taken up in clinical form are the following: lethargic encephalitis; thrombosis of cerebral arterioles with epileptiform attacks; paroxysmal tachycardia; peptic ulcer; gastric syphilis; lead poisoning with anemia of the pernicious type; idiopathic pernicious anemis; morbus maculosus neonatorum; pyloric and common bile-duct obstruction; sigmoid diverticulitis; and chronic ulcerative enterocolitis.

One concludes the reading of a clinic with the feeling that all that could be done in the diagnosis of the case and all that could be said in the interpretation of the findings has been done and said. That we question somewhat the strength of the foundation on which the author bases some of his conclusions is not important, inasmuch as his conclusions are generally shown to be correct. We are inclined to the belief, however, that his ultra-detailed processes of diagnosis and thought appeal rather to the physician who is in a position to analyze cases as does Doctor Smithies (and, therefore, is in no great need of his methods) than to the physicians whose practice is not confined to internal medicine, and who crave brief, incisive hints along modern lines. And should it not be our purpose to reach the average reader in our clinical teaching?

One of the most interesting features of this type of publication—and it is apparently gaining in favor—is the light it throws upon our methods of teaching. The didactic, the textbook method, is being superseded more and more by the case method, whether in the class room, in the small bedside clinic, or in the form of clinical lectures, and to this change we must heartily subscribe in view of the frequent deviation of the cases from the type. The textbook still has its place but only as a book of reference.

The material in these clinics is happily arranged and the author's style attractive. The numerous illustrations are excellent and together with the statistical tables add much to the value of the number. Doctor Smithies deserves praise for his versatility, thoroughness, and energy.

THE ITINERARY OF A BREAKFAST. By J. H. Kellogg, M.D., medical director of the Battle Creek Sanitarium.*

Doctor Kellogg's description of the passing of a breakfast through the food tube is written in a very entertaining manner and in popular language. It is obviously written for the layman, and for him there is much information. The intestinal tube is described as a route having ten gates and several stations through which food must travel before being used by the body. The method of procedure under normal conditions is given and some of the things which may occur to retard the progress of the food. Suggestions for overcoming these obstacles are given, and recommendations for diet.

Pertinent Paragraphs for Physicians. Quickly Read and Easily Digested

WHAT IS CINCHOPHEN

Cinchophen, Abbott, is Phenylcinchoninic Acid. Cinchophen, Abbott, has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association and was ordered in large quantities during the war by the United States Government.

Cinchophen, Abbott, stimulates the kidneys so as to increase the amount of urine and has a selective action on the excretion of uric acid, which is increased in greater ratio than the increase in the amount of urine. Cinchophen, therefore, effects a reduction of the uric acid content of the blood.

Cinchophen, Abbott, is useful wherever it is desirable to increase the flow of urine and the excretion of uric acid. Indications for its uses are gout, rheumatism, sciatica, neuritis and gonorrheal joint disease. In gouty conditions it is generally admitted to be the remedy of greatest value.

THE SERIOUSNESS OF SLEEP

Every doctor has seen how wakeful nights wear out a patient's strength and how a few hours of sound, refreshing slumber change the patient from a nervous wreck into a cheerful, reasonable human being.

Many remedies have been used for the induction of sleep, but most of them have been superseded by Barbital, or, as it was formerly known, Veronal. This remedy is efficient, it is nearly free from depressant action, and, under normal conditions it does not induce habit formation. So important is this remedy that when German Veronal was unobtainable in this country, several American manufacturing houses were asked by the United States Government to undertake the problem of its manufacture.

The Abbott Laboratories was one of these, and, working under great difficulties, it was able to produce large quantities of it for the American government for our soldiers and sailors, and it is now manufacturing Barbital of the best quality in quantities large enough to meet the civil demands. Specify Abbott's when prescribing Barbital.

JANUARY SUGGESTIONS

Good work; good drugs, larger practice.
Better fees. Closer collections.

The ideal antiseptic for everyday use Dakin's Chlorazene.

Dr. Wm. H. Wilcox, in The Lancet, advocates the more extensive use of bile salts therapeutically. Try Bilein (Abbott) in your cases of jaundice and as an adjuvant in the treatment of Cholelithiasis

Coughs and Colds Yield to Calcidin

Are you using Bacterins? Get the Abbott Price List.

Digipoten (Abbott) is the American-made Council-passed, digitalis preparation. Try it.

Can you clean a wound with soap? Neutral Sodium Soap (Abbott) is non-irritating and does not injure the skin.

Convenient branch offices are maintained by The Abbott Laboratories in New York City, 31 E. 17th St.; Seattle, 225 Central Bldg.; San Francisco, 371 Phelan Bldg. Also agencies in Los Angeles, Calif., Toronto, Canada, and Bombay, India. Wholesale druggists and the retail trade are also stocked with Abbott specialties.

BOOKS OF THE MONTH

(Continued from Page 22)

Contrary to the belief of the majority of our nutrition experts, the author states that "nuts give completeness to a diet from which milk, eggs, and meat are excluded."

In his opinion the evacuation of the bowels should occur three or four times daily; if limited to once daily, constipation exists. He warns us, also, to "Beware of the x-ray tyro. There are in the United States possibly one hundred x-ray specialists whose examination of the alimentary tract may be regarded as of value and whose conclusions may be trusted as fairly reliable, but the chances are very great that our estimate is far too large."

The charts showing the food *en route* are interesting and require no technical knowledge thoroughly to comprehend them.

Both the layman and the professional will find this a book worth reading.

RECLAIMING THE MAIMED. A Handbook of Physical Therapy. By R. Tait McKenzie, M.D., Major, R.A.M.C., professor physical therapy, University of Pennsylvania.*

In this small book McKenzie gives a simple description of the physical-therapeutical means by which many of the war injured have been rehabilitated and have been sent back into active life with bodies capable of fighting in the struggle for existence. The writer describes the usual galvanic and faradic apparatus and their use. He devotes a chapter to hydrotherapy; radiant heat and light lamps are dealt with, and their uses are briefly indicated. The mechanical devices used in several large Canadian hospitals are described and also a system of gymnastic exercises. "Aimless rubbing is as useless as waving a palm leaf fan if the operator be weak and timid, but it has additional possibilities of doing much harm if the operator, besides being ignorant, is rough and strong." With this introduction the subject of massage is opened, but the reader notes that purposeful, well planned manipulations have a very important place. The last few pages are devoted to methods of masking unsightly repulsive facial deformities.

PSYCHOSES OF THE WAR, Including Neurasthenia and Shell Shock. By H. C. Marr, Lt. Col., R.A.M.C., (Temp.), doctor of medicine, Fellow of the Royal Faculty of Physicians and Surgeons, Glasgow; neurological consultant to the Scottish Command; H. M. Commissioner of Control for Scotland; formerly specialist in nervous diseases of the troops in Malta (1915-1916); physician superintendent of Glasgow District Mental Hospital, Woodilee, Lenzie; and Mackintosh Lecturer in Psychological Medicine, St. Mungo's College Glasgow.†

"The psychoses of the war have revealed no new mental trait, but the war itself has rendered many who were unable to play a useful part in the battle of life less useful, and in many cases unable to do so. After the war there will be many problems, and of these problems not the least will be how to make fit those who are no longer able to return to their original duties, and to consider under what circumstances their usefulness and well being can be effected." In the solution of these problems this book by Lt. Col. Marr will surely be of considerable help, not only to the psychiatrist but to the general practitioner who will meet these cases in his practice.

The introduction to the book deals with the relationship

FOR DIET CONTROL IN INFANT FEEDING

The choice of these dependable products affords the physician convenient means of selecting food mixtures suited to the individual requirements of individual cases.

MEAD'S DEXTRI-MALTOSE NO. 1

(With Sodium Chloride 2%)

For general use in infant feeding. Especially indicated in infants recovering from diarrhoea, infants with feeble powers of digestion who have tendencies to diarrhoea. Valuable as an addition to Protein Milk.

MEAD'S DRY MALT SOUP STOCK

For difficult feeding cases. Indicated in marasmus, weight disturbance (failure to gain), infants afflicted with recurrent diarrhoea from intestinal indigestion, and those cases occasionally met which do not do well on milk, water and sugar mixtures.

MEAD'S DEXTRI-MALTOSE NO. 3

(With Potassium Carbonate 2%)

For use in constipation, when boiled feedings are used, or where the addition of potassium to the infant's diet is indicated.

Full information regarding these products furnished on request.

MEAD JOHNSON & CO. **Evansville, Ind.**

Concentrated Nourishment With Slight Digestion Tax

Borden's Malted Milk is prepared by an exclusive, improved process whereby malt ferments acting on the proteins convert them to partial peptones.

This partial predigestion lessens the strain on the gastro-intestinal tract and renders Borden's Malted Milk, with its concentrated nourishment, a safe and valuable ingredient of diet throughout typhoid fever, or whenever digestion and assimilation are subnormal.

If taken piping hot before retiring it induces restful and refreshing sleep.

Samples, analysis and literature on request.

BOOKS OF THE MONTH

(Continued from Page 24)

of normal to abnormal mental processes with the anatomy and physiology of cerebration and with the means of observation of mental phenomena. In the introduction one finds the classification of mental affections: Neurasthenia, psychasthenia, mental deficiency (infantile), mental enfeeblement (adolescent), toxic psychoses, and organic psychoses (cerebropathies). This classification is further subdivided until practically all of the mental affections can be found. Neurasthenia, shell shock, hysteria, which Marr terms neurasthenia of toxic origin, psychasthenia, and all the other divisions of the general classification above given are discussed.

The appendix contains a chapter on the nature and method of examination of the cerebral spinal fluid, and special reference is made to the colloidal gold test, while at the end of the book there is a very interesting series of charts for mental "case taking." The book is well illustrated and well printed throughout, and on the whole furnishes a most useful and instructive collection of knowledge on the important matter it covers.

ESSENTIALS OF SURGERY. A Textbook of Surgery for Student and Graduate Nurses and for Those Interested in the Care of the Sick. By Archibald Leete MacDonald, M.D., the Johns Hopkins University; formerly in charge of the department of anatomy, University of North Dakota; lecturer on surgery, Nurses Training School, St. Luke's Hospital, Duluth, Minn.*

The book covers the principles of surgery in an elementary way. The matter is presented simply. Only general statements are made concerning etiology, pathology, and the natural course of the disease. The treatment is briefly indicated. Demonstrations for class work are described at the end of every chapter. These demonstrations are very good and will prove helpful to the lecturer.

The book is not complete enough in detail for a study book for class work, but it is an excellent guide book for the teacher.

THE SCIENCE OF EATING. How to Insure Stamina, Endurance, Vigor, Strength, and Health in Infancy, Youth, and Age. By Alfred W. McCann. Author of "Thirty-Cent Bread," "Starving America," etc.†

"In the preface of this book the author states that in his opinion the true conditions in regard to foods will not be made public through the press, neither will they be remedied by legislation; therefore, through the public schools the American children should be taught "the relationship of foodless food to sickness and death, the relationship of natural food to health and life." The most prevalent and widely recognized evils in food production, dietary habits, and principles of nutrition are discussed in a very positive manner, though the author's ideas do not always accord with those who are accepted as our best authorities in nutrition.

To put this book into the hands of school children would be a great injustice, not only because of the highly dramatic way in which the text is written, but because of the content of some of the statements. The following selected at random, is on page 33: "New blood arrests disease, walls up tuberculous lesions, and the patient, if not in the very shadow of death, is reclaimed. New red blood depends upon food, on food alone." This is placing

—cover the Entire Field

The publications of The Modern Hospital Publishing Company cover the entire field of administrative medicine. Their text matter appeals to every individual engaged in health and welfare work and administrative medicine and to those executives responsible for the purchase of equipment and supplies for the care of the sick and the maintenance of the health of the nation.

THE MODERN HOSPITAL is a generously illustrated monthly magazine devoted to the building, equipment and administration of hospitals, sanatoriums and allied institutions and to their medical, surgical and nursing service. THE MODERN HOSPITAL averages over two hundred and fifty pages each month and reaches over 90 per cent of the total bed capacity of the entire field.

MODERN MEDICINE is a well illustrated monthly magazine devoted to medical and health progress for physicians and others interested in administrative, industrial and social health problems.

The Modern Hospital YEAR BOOK is a Buyers' Reference Book of supplies and equipment for hospitals and institutions, including an annual review of hospital progress and interesting discussions of institutional buying problems. This valuable book is loaned without charge to hospital executives and others responsible for the purchase of hospital equipment and supplies. The 1919 edition consists of nearly eight hundred pages and includes the condensed catalogs of over two hundred firms serving the hospital field.

A sample copy of either of our magazines will be gladly sent upon request. A copy of the 1919 YEAR BOOK will be loaned to any institution or individual entitled to it.

BOOKS OF THE MONTH

(Continued from Page 26)

a great responsibility on food alone, giving no thought to the conditions which may prevent the body from assimilating the foods necessary to fulfill these claims. Proper methods of cooking food materials, normal functioning of the organs of digestion, good hygienic conditions; in fact, correct habits of living and correct dietary habits are generally conceded to be helpful in arresting disease and in restoring patients to health.

Statements are found throughout the entire book which are founded on fact, but do not tell the whole truth, or which may be misleading to the public for whom the book was evidently written.

Mr. McCann calls the Deity into the discussion frequently. He condemns "modern refining processes" and some of our more conservative food specialists with equal emphasis. While these methods may be effective in attracting attention when talking to an audience, they are less desirable in print.

"Science of Eating" is a large volume, consisting of 408 pages, and contains many good points stated in a very pertinent way. Many people might be persuaded to reform their dietary habits through reading this book, but it will scarcely meet the needs of the true student.

ORGANIZATION OF PUBLIC HEALTH NURSING. By Annie M. Brainard.*

Since public health nursing is a profession still in process of evolution, with rapid changes taking place, any book on the subject of its organization must necessarily be of a tentative nature, rather than didactic. In this little volume, the author has tried merely to point out a few general principles which seem to her to be fundamental, and to describe various forms of organization that have been tried and found satisfactory. The rapid development in public health nursing resulting from the war makes it necessary for the public health nurse to organize her work efficiently. The author, after long experience in the public health nursing world in a city notable for its organized health effort, is well qualified to state the general principles of efficient organization as well as to place before the novice valuable suggestions regarding simple matters of detail.

The importance of the public health nurse having some form of organization behind her, no matter how highly trained she may be, is first brought out by the author. The organization back of her may be either public—that is, municipal, state, or federal; or it may be private—that is, supported and controlled by private individuals. It may be very simple or very complicated; an independent organization or a division of some other organization. The qualifications of the public health nurse are stated by the author, as well as the fundamental principles which she should keep in mind.

In the chapter on "Forms of Organization," some of the principal forms of organization which have been tried and found satisfactory are outlined. Five charts of organization plans present the subject in a helpful, graphic way. How to organize public health nursing in a new community is described, with suggestions as to the personnel and duties of the board of directors and the various committees—finance, nurses, and supply. The sections on records, statistics, and reorganization contain illustrations of history charts and different methods of reorganization.

BOOKS OF THE MONTH

(Continued from Page 28)

THE ANATOMY OF THE PERIPHERAL NERVES. By Melville Paterson, M.D., F.R.C.S., assistant inspector of Special Military Surgical Hospitals, professor of anatomy in the University of Liverpool, examiner in anatomy at the Royal College of Surgeons of England, etc.*

The object of this book is to provide a brief account of the peripheral nerves for the use of students and surgeons, particularly for those engaged in military orthopedic work.

The purpose, which is described in the preface, is admirably fulfilled in the text. The descriptions are brief and clear and the diagrams, of which there are a great number, are to the point.

There is very little that can be said about a book of this kind, except to point out its purpose and to indicate how that purpose has been carried out. The accuracy of the descriptions is to be taken for granted because much of the anatomical detail is taken from well-known anatomies, particularly from Cunningham. The Oxford Medical publications have in the last few years brought out a number of small manuals of this kind. They have proved themselves of service on account of their well chosen selection of subjects and on account of the clear way in which they are written. This book of Paterson's is one of the most useful of them. It is a book of easy reference and is particularly adapted to the neurologist and surgeon who is dealing with the problems clustering about the traumatic conditions involving the peripheral nervous system.

CEREBROSPINAL FLUID IN HEALTH AND IN DISEASE. By Abraham Levinson, B.S., M.D., associate in pediatrics, Northwestern University Medical School. With a foreword by Ludwig Hektoen, M.D.†

This is a very valuable little book on a subject that is one of the most important of present-day problems in clinical neurology. The author has sensed the significant phases of his subject in an unusual way and he has also felt the real difficulties of the practitioner who seeks to make the best use of the data that the study of the spinal fluid may furnish him. Out of the maze of conflicting opinions that have clustered about the subject he has been able to point out the significant facts that have been gained and upon the debatable questions he has preserved the right kind of skepticism.

With this book the clinician can make use of the diagnostic aid which the study of a spinal fluid furnishes and will escape the pitfalls which lie ready at hand if too much weight is placed upon theoretical interpretations of doubtful evidence.

The chapter on the history of the spinal fluid is especially to be commended because of its brevity, accuracy, and incisiveness. The conception of the spinal fluid as a protective agency fulfills the known facts in the question much more than does any other explanation, and upon that basis its place in the mechanism of the physchology of the nervous system seems assured.

The description of methods of examination are clearly presented and the deductions from the data found in pathologic fluids are given in a precise and clear manner. There is a bit of confidence in the curve in the Lange Test in the case of tubercular meningitis that seems scarcely justified by experience. Not enough importance perhaps is given to the syphilitic curve in the same test. Such views are due, no doubt, to the fact that the author has

BOOKS OF THE MONTH

(Continued from Adv. Page 30)

found most of his experience in pediatrics and it is upon this that the point of view of the book seems to be based.

The style of the book is good and it reads well and easily, a rare quality in medical books as the reviewer sees them. A word must he said in praise of the introduction written by Hektoen. This is a model of a prefatory note and serves to put the reader in a good humor through sheer delight at a difficult thing well and gracefully done.

TUBERCULOSIS IN MASSACHUSETTS

The increase in the Massachusetts State curve for tuberculosis is not to be ascribed wholly to the effect of better notification. The decline of the incidence of pulmonary tuberculosis has been more marked in the cities than in rural districts. Hence reorganization of territory is recommended to fill any existing gaps. Consulting service at the call of physicians to supplement nursing service, and better educational methods are to be instituted.

DEPARTMENT OF HYGIENE AT HARVARD

The will of the late Dr. Henry K. Oliver provides a fund for the establishment and for the liberal maintenance in the under-graduate department at Harvard of a full professor of hygiene, the professor to be a regularly educated physician of marked ability and industry, and of a temperament likely to enlist readily the confidence of young men. His chief function is to promote recreation and physical exercise among under-graduates of sedentary and over studious habits, and to instruct them in physical laws for the preservation of their health.

HEALTH ACTIVITIES IN COLLEGES

The rigid regulation by colleges and universities of everything pertaining to the hygiene of students as a trend in education in the past few years is discussed by Dr. John Sundwall, of the University of Minnesota, in *Public Health Reports*, November 7, 1919. The aims, organization, and activities are fully analyzed and university health service is declared to stand for positive health.

The same issue contains an exposition by L. L. Lumsden, Surgeon, of the United States Public Health Service, of the plan for rural health work. Preliminary to the cooperative plan of county health work rural sanitary surveys were conducted in eighteen counties located in sixteen states.[1] The conclusion that rural sanitation is needed, that it is feasible, and that its cost is less than the cost of illness, has directed service in this field toward assisting and actively cooperating with county and state health organizations in the establishment and maintenance of whole-time health organizations for continued cooperative health work in counties or townships as units of rural district government. County demonstration work in rural sanitation is now being conducted by the Public Health Service on as extensive a scale as the appropriations admit with results that warrant a radical extension of the business, says Doctor Lumsden.

Two tuberculosis hospitals are to be built by the state of Idaho. One will be in the northern part and the other in the southwestern.

[1] The findings and results of these surveys are reported in Public Health Bulletin No. 94.

The nutrient value of Virol illustrated in a series of cases, particulars of which have been supplied by medical men.

CASE No. 2

THE value of VIROL is well shown in this case. This child weighed 17 lbs. at 40 weeks and is in perfect health.

AFTER VIROL

SHOWING the handicap the baby had to overcome. This picture was taken at age 7 weeks—weight 2 lbs. 13 ozs., every food having failed and not able to digest milk itself.

BEFORE VIROL

Virol is valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow Fat and Beef; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars: 50c, $1.00 and $2.00

Liberal samples and interesting literature sent to physicians on request.

VIROL is concentrated food, prepared with scientific skill from most nutritious substances. The proportions are carefully adjusted to diet formulae laid down by up-to-date physiologists.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex *to be* and *to do* and *hold her to this inspiration* by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Susanna Cocroft

624 Michigan Boulevard Chicago

FEDERATION OF BIOLOGICAL SOCIETIES

The Federation of Biological Societies, of which the American Physiological Society is a member, held its thirty-second annual meeting at Toronto, Ont., December 29-31.

BUBONIC PLAGUE

The seventh case of bubonic plague this year in New Orleans is reported, and with it comes the announcement of the president of the dock board that all port facilities of New Orleans are to be rat-proofed at an expenditure of around $2,000,000. All other dock facilities will gradually be rat-proofed in the interest of plague prevention and public health.

PROVE VALUE OF MEDICAL INSPECTION

The beneficial results of medical inspection in the schools of Cleveland, Ohio, which has been in effect for several years have proved the value of the system, and are especially important now that Ohio is planning a more comprehensive system in its public schools. Statistics for the past year show that 46.9 per cent of the defects found have been eliminated, compared with 35.4 per cent for the previous year.

ACADEMY OF MEDICINE ELECTS OFFICERS

The New York Academy of Medicine on December 4, 1919, at the meeting in New York, elected the following officers: Dr. Rufus I. Cole, first vice-president for three years; Dr. W. Gilman Thompson, trustee for five years; Dr. Sidney R. Burnap, member of committee on admission for five years; Dr. Cary Vogel, member of committee of library. The term of the president, Dr. George David Stewart, does not expire until 1920.

LOS ANGELES NARCOTIC CLINIC

Los Angeles has announced plans for the establishment of a municipal dispensary and clinic for the decreasing dosage treatment of narcotic addicts. The municipal clinic will be open mornings and evenings. It will be in charge of physicians working under the supervision of the Health Commissioner, a recognized druggist of ability, and nurses. It is expected to prescribe morphin and other narcotics just enough above cost price to bring the clinic up to a self-sustaining basis.

PSYCHOLOGY AS RELATED TO MEDICINE

More than twenty physicians and dentists are receiving from the extension division service of the University of California a course of lectures on psychology in its relation to medicine. This course is part of a plan of the University to offer its highly technical courses to any group of persons qualified to take the instruction, and similar courses in psychology will be given in San Francisco in January.

GYNECOLOGISTS AND OBSTETRICIANS ORGANIZE ASSOCIATION

At a conference of gynecologists held in Brussels, Belgium, the last week in September, the International Association of Gynecologists and Obstetricians was organized, with the following among the officers: president, Dr Franklin H. Martin, of Chicago; secretary-general, Dr. Frank F. Simpson, of Pittsburgh; councilors, Dr. J. Riddle Goffe, of New York; Dr. Thomas J. Watkins, of Chicago, and Dr. George Gray Ward, Jr., of New York.

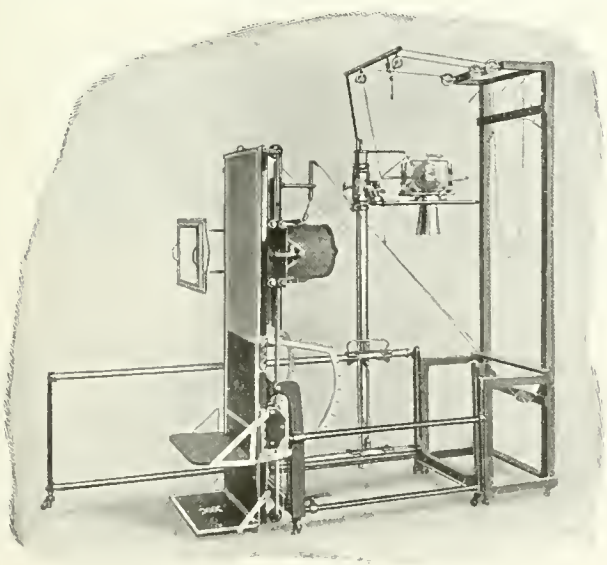
For Group Clinics—For Industrial Hospitals



When you are interested in an x-ray equipment representing the most advanced ideas consistent with conservative practice, to facilitate and expedite your work, then investigate a Meyer equipment.

MULTOSCOPE, a stereo-radiographic table with tube holder and radioscope for vertical, horizontal and inclined position, with self-contained aerial and high tension switch.

KLINOSCOPE, a fluoroscopic apparatus for vertical and horizontal fluoroscopy.

TRANSFORMERS, with a marked efficiency and conservation of tubes.

DUPLEX STEREOSCOPE, enabling the surgeon and roentgeonologist to observe the view at the same time.

A competent installer and service man for every installation

—1860-1920—

With the coming of 1920, the house of Reed & Carnrick will round out

Sixty Years of Faithful Service to the Medical Profession

From the inception of our business we have ever sought the friendship and confidence of physicians, and whatever results we may have obtained, we do not hesitate to attribute largely to the splendid co-operation that has been given us by the medical profession.

Therefore, in calling attention to this—our Sixtieth Anniversary—we wish to thank our many medical friends not only for their unfailing interest and good will, but also to assure them that, as in the past, we shall continue to regard their confidence as "our greatest asset."

REED & CARNRICK

Jersey City, N. J.

DIETETIC CENTERS FOR THE TUBERCULOUS

A plan has been initiated looking toward the establishment in all hospitals of the state of Pennsylvania of dietetic centers in which dietitians furnished by the Tuberculosis Society of Philadelphia will instruct classes in the preparation of simple foods and the making of model menus designed to supply the greatest amount of strength. The first class attended by state nurses is being held at Jefferson Department of Diseases of the Chest, 238 Pine Street, Philadelphia.

PROGRESSIVE WORK AT HARPER HOSPITAL, DETROIT, MICH.

Harper Hospital, of Detroit, Mich., has established in connection with the out-patient department an oral surgery clinic which devotes particular attention to the treatment of cleft palate and harelip patients. This important extension of medical service is under the direction of C. L. Straith, M.D., D.D.S. The progressive spirit of this institution is also indicated by the requirements in their training school for nurses of special studies in the realm of public health nursing.

INTELLIGENCE TESTS IN PUBLIC SCHOOLS

Mental tests such as are used in the army, if experiments now being made prove as successful as is hoped, will be used in the public schools. Such intelligence tests have been used in schools for some time on individual children, but the new plan provides for handling them in groups, even whole classrooms at a time. In the preliminary trials tests were made on about 5,000 children. As a result, two series of tests were selected which will again be tried on several thousand more children in order that they may be further perfected before they are finally offered to teachers of the country.

NEW FIELD FOR MOTION PICTURES

Biology, the natural sciences, physiology, clinical pathology, practical hygiene, and sanitation offer an excellent opportunity for the motion picture camera, in the opinion of Charles F. Herm of the American Museum of Natural History. The biological field has been somewhat neglected, he says. Numerous semi-biological films have been released, none of which, however, have been displayed as successfully as if the same subjects had been treated by specialists in their fields of work. In the latter event, the educational value of the films would have been greatly improved without diminishing in any way the interest to the general public.

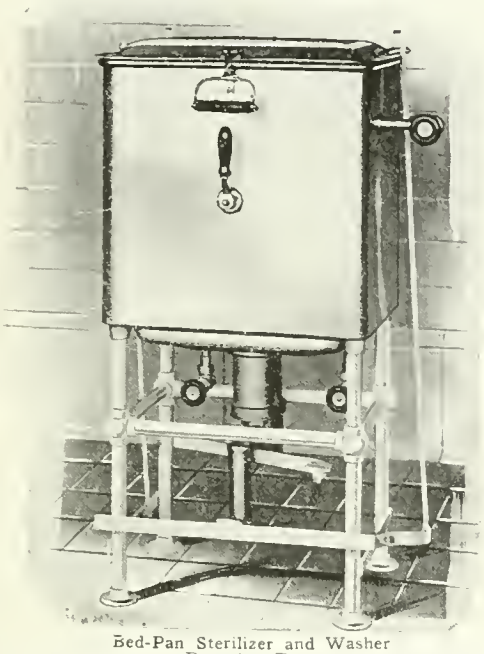
BOULDER COUNTY SOCIAL SURVEY

A survey of Boulder County, Colo., under the direction of the Bureau of Education and Research of the Mountain Division of the Red Cross, the Bureau of Public Welfare, of the Extension Division of the State University has been undertaken which will include all matters of health and sanitation, county and municipal administration, business and industry, recreation, adult and juvenile delinquency, mental deficiency, and relief work. A "Know Your County Week" is planned for the conclusion of the survey in order to disseminate the facts assembled. Provision is made for the follow-up work which may be shown to be needed, and appropriate organization has been made for carrying out special phases of the program adopted. Sound health work will be based upon the actual facts disclosed by the survey.

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT



Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it. Investigate "AMERICAN" sterilizers and you will find that the secret of their success is HIGHEST QUALITY and LONGEST SERVICE.

AMERICAN STERILIZER COMPANY, Erie, Pa.

REMEMBER ARISTON CEREAL COFFEE BLENDS

ARE NOT COFFEE SUBSTITUTES

At present prices of coffee they offer a means of making important savings, without reduction of beverage quality.

You are sure to like them better than any coffee you can buy at the same price per pound.

They add a nourishment valuable as an item of diet, and they reduce the caffeine content. They therefor make a many-sided appeal.

BEVERAGE QUALITY—COST SAVING
FOOD VALUE—CAFFEINE REDUCTION

We supply the following blends:

Blend No. 1, per pound **38c**
Blend No. 2, per pound **36c**
Blend No. 3, per pound **34c**
Blend No. 4, per pound **32c**
Blend No. 5, per pound **30c**

Let us ship you a trial order of 100 pounds. We pay the freight and guarantee the goods. You may return at our expense, if not pleased.

Overton and Denno's

The Health Officer

By Frank Overton, M. D., D. P. H., Sanitary Supervisor, New York State Department of Health; and Willard J. Denno, M. D., D. P. H., Medical Director, Standard Oil Company. Octavo of 500 pages, illustrated. Price, $4.50, postpaid.

This new book, published in 1919, contains the information the average Health Officer must have in order to discharge his duties. It tells him what to do, how to do it, and why he should do it. It describes the various activities in which a Health Officer engages; his relation to boards of health, physicians, social agencies, and the public; his qualifications and methods of work; the various diseases and insanitary conditions with which he deals, and the scientific principles upon which preventive medicine is founded. The work is the result of ten years' experience in this field. While the book is designed primarily for Health Officers, it has a decided value to public health nurses, members of boards of health, social workers, teachers, and all others interested in organized health work.

The Modern Hospital Publishing Co., Inc.

58 E. WASHINGTON ST., CHICAGO.

CHILD HYGIENE ASSOCIATION ELECTS OFFICERS

At the annual meeting held in December, 1919, at Asheville, N. C., the American Child Hygiene Association elected the following officers: Dr. Philip Van Ingen, president; C.-E. A. Winslow, M.D., New Haven, Conn., president-elect; Drs. W. M. Chapman, Montreal, and Howard C. Carpenter, Philadelphia, vice-presidents; Henry F. Helmholz, Evanston, Ill., secretary, re-elected; Austin McClanahan, Baltimore, treasurer, and Miss Gertrude B. Knipp, executive secretary, re-elected.

PRESIDENT OF THE AMERICAN COLLEGE OF SURGEONS

Dr. George E. Armstrong, of Montreal, was elected president of the American College of Surgeons at the Ninth Annual Congress, held recently in New York. Doctor Armstrong is professor of surgery in McGill University, Montreal. Honorary memberships were conferred on Major Generals Sir Anthony Bowlby and Sir Robert Jones, of the British Army; Dr. Irving H. Cameron, of the University of Toronto; and on Prof. Theodore Tuffire, of Paris.

ANTI-GASEOUS GANGRENE SERUM

The 1918 report of the Rockefeller Foundation announces the production of an anti-serum not only for the gas bacillus, *B. welchii*, but also for other anaërobic bacteria occurring in cultivated soils. Experiments to enlarge the therapeutic properties of the anti-gaseous gangrene serum are so well advanced that it is safe to conclude that a permanent addition has been made to the measures now available for preventing gaseous gangrene, or for curing it when it arises in connection with industrial and other accidents of civil life.

DO SHORTER HOURS DECREASE OUTPUT?

The return of thousands of demobilized spinners and piecers to their old employment will indicate more definitely whether or not the reduction of working hours in cotton and other industries has resulted in more intense application and the maintenance of the previous output. During recent negotiations between employers and operatives, says *Commeree Reports*, the former sought to embody a clause for the speeding up of production in order to counterbalance the loss in working time, but this was not accepted as it was considered that the operatives worked as hard as they should be expected to do.

PROGRAM OF PUBLIC HEALTH SERVICE

Experience has shown that the best cooperation in Federal health work can be secured from the Federal aid extension principle, states a bulletin which has been issued by the United States Public Health Service, outlining its program for after the war needs. This bulletin appears as Supplement No. 35 to Public Health Reports.

The bulletin outlines the activities which the Public Health Service proposes to follow up during the times of peace under the following headings: (1) industrial hygiene; (2) rural hygiene; (3) prevention of the diseases of infancy and childhood; (4) water supply; (5) milk supply; (6) sewage disposal; (7) malaria; (8) venereal diseases; (9) tuberculosis; (10) railway sanitation; (11) municipal sanitation; (12) health standards; (13) health education; (14) correcting of morbidity reports; (15) organization and training for duties.

Cafeterias and Lunch Rooms Are Common Sense Health Insurance

The physical and mental well-being of employes are important factors in the efficiency of every industry. Faulty nutrition is recognized as a detrimental condition for the satisfactory progress of school children, as well as preventing 100 per cent service from the employe. Properly conducted Cafeterias have proved their worth in bringing the individual up to par in both industries and schools.

Rest and Club Rooms, considered essential by many employers, add that element of good-will necessary for the complete co-operation of the employe.

As the largest Cafeteria and Lunch Room Equipment house, we are prepared to design a Cafeteria or Lunch Room to meet any special needs, or to advise on correct equipment and installation. Regardless of what is required, we can supply it—at a saving. We furnish everything for Rest Rooms or Industrial Clubs at a saving to you of time and money.

Successful installations all over the country testify to our ability in these lines. Let us assist you in the formulation of your plans.

Always Ready for Immediate Use

In Gonorrhea

In genito-urinary work, and especially in the treatment of gonorrhea, acute and chronic, Hyclorite cleans sloughing tissues, destroys toxins and stops discharges without irritating tissues. It actively assists repair.

Hyclorite is proving particularly successful in the treatment of old cases.

HYCLORITE

Concentrated Sodium Hypochlorite

Hyclorite requires no testing.
It is always ready for use.
Just add water and apply.
No waste. No waiting.
Non-irritating properly diluted.

Price, 32-oz., $1.25

AID FOR NEGRO MEDICAL STUDENTS

An offer of six scholarships of $1,200 each for negro graduates of American medical colleges who wish to take postgraduate work in pathology, bacteriology, physiology, pharmacology, or physiological chemistry has been made by Julius Rosenwald, of Chicago, the announcement having been made by the General Education Board of New York. Appointment will be made next year, selection of the candidates to be made by the following committee: Dr. William H. Welch, Johns Hopkins School of Public Health, chairman; Dr. David L. Edsall, dean of Harvard Medical School; Dr. Victor C. Vaughan, dean of the medical department, University of Michigan. Abraham Flexner is secretary.

THE WESTERN ROENTGEN SOCIETY

The Western Roentgen Society held its annual meeting in Chicago, December 10, 11, and 12, at the Hotel Sherman. The meetings were exceptionally well attended. The papers demonstrated the ever widening possibilities of the application of the various radiologic measures to the practice of medicine. The keynote sounded throughout was for conservatism, seeking a closer understanding and cooperation with the profession in order to bring out to the utmost the various utilities of radiologic endeavor.

The variety of subjects covered, the new ideas, and the new fields of research and progress attest to the broadening out of the radiologic field to take its place among the great divisions of medicine.

On account of the broadening of the scope of the work, the name of the organization is to be changed from the Western Roentgen Society to the Radiological Society of North America, and the journal now known as the *Journal of Roentgenology* is to be changed to the *Journal of Radiology*. The publication committee and editorial staff were increased in number and so arranged as to represent the various fields of work covered under radiology.

A series of very valuable papers was presented covering equipment, technic, research, and clinical interpretation. A notable contribution was offered by Dr. B. H. Orndoff, of the Frances Willard Hospital, Chicago, who reported his research work on pneumo-peritoneum, a technic which enables the distinction of organs in the upper abdomen and which should be of great value in determining the operability in a given case,—of cancer, for instance,—or be the means of detecting early involvement and so bring the patient to operation well within the safe limit. Cases in point were cited by Dr. H. J. Ravold, of St. Joseph, Mo.

At a joint meeting with the Chicago Medical Society, C. R. Bardeen, M.D., Madison, Wis., presented a paper on "Some Aspects of the Examination of the Heart by Roentgenology," and Russell H. Boggs, M.D., Pittsburgh, Pa., read a paper on "Combining Radium and Roentgen Rays in Malignancy." "Radium in the Treatment of Thyroid Disease" was the subject of a discussion by Henry Grote, M.D., of Bloomington, Ill.

The election of officers placed the following men in charge for the ensuing year: Dr. A. F. Tyler, Omaha, Neb., president; Dr. Alden Williams, Grand Rapids, Mich., president-elect; Dr. E. A. Merritt, Washington, D. C., first vice-president; Dr. W. S. Lawrence, Memphis, Tenn., second vice-president; Dr. Lloyd Bryan, San Francisco, Calif., third vice-president; and Dr. M. J. Sandborn, Appleton, Wis., secretary-treasurer. The next meeting will be held in New Orleans, the Friday and Saturday just preceding the meeting of the American Medical Association.

Semdac Liquid Gloss

(A SUPERIOR POLISH)

Makes Dust Danger-less

IN the cleanest hospital dust is everywhere. It cannot be eliminated, but Semdac Liquid Gloss will control it.

The hospital superintendent knows, that in his institution, dust is dangerous. He knows that at every movement in a room these tiny particles of germ-laden matter float in the air, threatening his patients. Semdac will control the dust.

Semdac is odorless, and may be used, at any time, without interfering with the comfort of the patients.

Semdac Liquid Gloss—the odorless cleaning agent—imprisons dust in a film, which renders it danger-less; also it minimizes the amount of free dust in a room.

Semdac Liquid Gloss, freshens and brightens all finished wood, metal and enameled surfaces, furniture and floors, for it polishes as it cleans. It is made in the laboratories of the Standard Oil Company (Indiana).

CLINICS UNITE FOR MIND CASES

The state hospitals and the Commission for Defectives in New York have united to form centers where facilities are provided for expert examination of cases showing mental disease or mental defect. Consultation will be available to individuals who find themselves unable to carry on their work or continue in their ordinary associations because of depression, weariness, forgetfulness, lack of ambition, or poor judgment. Parents, teachers, or physicians may refer any children who are slow in development or abnormal in behavior. In any case, the advantage is apparent in care and training adapted to the needs of the individual.

WILL PAY MATERNITY BENEFITS

Motherhood insurance, a part of a plan announced recently by the American Woolen Company, of New York, assures every prospective mother in the employ of that corporation of four weeks' benefits without cost to her.

The company also announced to its employees a plan of free sick and accident benefits effective at noon, December 1. The plan includes every employee of the American Woolen Company and its subsidiary companies. The basis on which these benefits are computed is as follows:

No employee is insured under the plan who is not on the payroll of the company on December 1, working for full time and full pay. An employee who is not at work on December 1 because of disability, will be insured from the date of his return to employment on full time and full pay. After December 1, new employees will be eligible when they have been in the employ of the company for six continuous months.

Those on the payroll December 1, and who have been employed for less than six months, will receive forty per cent of their average weekly income. Those employed continuously over six months and not more than one year will receive 50 per cent of their average weekly income; over one year and not more than two years, 60 per cent; over two years and not more than three years, 70 per cent; over three years and not more than four years, 75 per cent; four years and over, 80 per cent.

No employee will receive less than $8 per week nor more than $30 per week, regardless of his average weekly earnings.

These benefits will cover all cases of disability arising from sickness or accident inside or outside of the worker's place of employment, and are supplemental and in addition to the indemnities provided by the compensation acts of the different states where American Woolen Company mills are located for accidents arising at occupation to the extent of the difference between the indemnities provided for by the above plan and the indemnities provided by the compensation acts of such states, except that new employees hired after December 1 will be entitled only to benefits as provided by the compensation act until after they have completed six months' continuous service.

The benefits will begin only after seven days' loss of time and will continue thereafter for a period not to exceed twenty-six continuous weeks, so that for accidents occurring at occupation the amount of indemnity paid beyond twenty-six weeks and the duration of indemnity beyond twenty-six weeks, shall be only that provided for by the compensation law of the state in which the mill in which an employee works is located.

Benefits for maternity cases for employed women will be for four weeks, in amounts dependent on length of service.

NOTES AND COMMENT

SWASHBUCKLING LEADERSHIP

THE medical profession has always held high ideals of scientific leadership. In professional associations the most careful scrutiny of candidates has been exercised before election to the scientific offices of the associations. The records of all medical societies are remarkably good in this respect. The ideals of the profession of medicine have been universally upheld.

In these days of delicate relationships in all social affairs one would expect to find the same high type of leadership guiding the medical profession in helping to solve the difficult problems confronting the profession, particularly in its relations to the public. Anything less is a menace to the profession and to the public. The professional ideals of the physicians should pervade the whole activities of the profession of medicine. There is no place for the demagogue or the swashbuckler.

But there is evidence of present danger in this respect. An example has prompted this editorial. In the city of Brooklyn, N. Y., the medical society has apparently abdicated its leadership in public matters and placed it in the hands of the so-called Professional Guild composed of doctors, dentists, and druggists. This Guild is promoted for the purpose of fighting health insurance and its work is carried on by an apparently irresponsible public health committee. The voice of this committee and of its chairman becomes the voice of the physician, and the profession must bear the stigma which may be brought to it by the self-appointed leadership which the Guild produces and over which the profession has no control.

This committee and its chairman have already justified the fears of demagogy and swashbuckling leadership. It has spread broadcast most vicious tirades against the promoters of health insurance. No words are too strong in the vocabulary of the chairman to describe what he considers the viciousness of the men and women who are supporting this measure. To quote from a pamphlet of this committee:

> Behind this Bill is an organization called the American Association for Labor Legislation, "Made in Germany" as part of the "infamous Kultur" and imported to this country by a Russian disciple of Bolshevism and "I-won't-workism"; its board of officers contains the names of hysterical men and women and vicious men and women who have no knowledge of or sympathy with the needs of working people and who believe that the working man does not know what is good for him and "they do," and they are willing to take lucrative positions under the Davenport-Donahue Bill to do him good and to "DO HIM —good"; these people are paid professional philanthropists, and busy-body social workers, protégés of the foundations; misguided clergymen; editors, and officials and financial backers of such "parlor Bolshevik" papers as *The Survey* and the *New Republic* and such inflammatory papers as *The Crisis* and the *Messenger*, which tend to encourage unrest and race rioting among negroes; supporters, defenders, associates of the forces of unrest known as the I. W. W. and Bolshevists; the disciples of Lenine and Trotzky, whose gospel is the destruction of those things worth while for which men and women have given their lives.

Such a statement could hardly come from any but an unbalanced personality. It was made of men and women who are known individually and collectively all over the country as able, patriotic, and sincere Americans. In the whole list of officers and advisory council of the American Association for Labor Legislation, numbering a hundred persons, there is not a single radical of any description. Many of the most eminent employ-

ers, labor leaders, physicians, educators, and public men and women are on the list of those who are denounced by this ignorant, indiscreet tirade of the so-called Professional Guild.

Among the great organizations which have declared for health insurance are the New York State Federation of Labor, twenty state and twenty national organizations of labor, the New York League of Women Voters, the national and state consumers' leagues, seven official state commissions, the National Catholic War Council, the Jewish Conference of Social Work, and scores of other organizations. To characterize a measure supported by all of these organizations in the terms used throughout the propaganda of the Professional Guild of Kings County is the silliest twaddle. The individuals who sign such stuff should not be allowed to degrade the whole medical profession.

MODERN MEDICINE stands for medical leadership in health insurance. We believe that it is not primarily the duty of the profession to promote or to oppose its coming, but rather to analyze the problems of sickness and the relation of health insurance to them, and to guide the formulation of legislation so that the function of medicine may be fully recognized and the work of the physician safeguarded for the public benefit as well as that of the profession. The burning intolerance of those who have usurped authority in medical circles in Brooklyn is destructive of this ideal and will react disastrously upon the profession.

MISUSE AND NON-USE OF LABORATORY TESTS

A CYNIC has said that the modern clinicians value a laboratory test directly as the distance of the laboratory from the bedside and as the square of the time taken in making the test. He might have added, "inversely as the number of vowels in the originator's name." There is much truth in this hyperbole that we do lean too heavily on the laboratory.

Aside from research, there are three ways of using a laboratory: (1) when really useful information can more certainly and more expeditiously be gained from a laboratory test than from clinical observation, or when confirmation of the conclusions drawn from the latter is necessary; (2) to gain time to look up a subject in the literature; or (3) to save ourselves trouble or to impress our patients. The first is the legitimate; the second a pardonable use; the third is only too common and is wholly to be condemned. It is as bad as the two equally common faults of neglecting the use of laboratory facilities in appropriate cases, and of putting the biochemist to great trouble while neglecting the clinical, and especially the dietetic observations which alone can give to his laboratory results sound clinical applications.

We have seen a complete series of the report forms on routine laboratory tests used in one teaching hospital. They covered half the surface of a good sized door. We wondered how soon in that hospital they got down to each "case" as a real human patient. Heart diagnosis is taught with the electrocardiagraph to the minimizing of the more convenient means of diagnosis, and this to physicians who will practise their art in the rural solitudes of Podunk or on the brumous shores of Nova Scotia.

A sample of a patient's blood having been sent to the laboratory for a Wassermann test, many clinicians seem to consider themselves dispensed from making an examination of the edges of the tibiae, of the eyes, and of the parts where signs of actual or of past lues may manifest themselves. The Wassermann is one of the most valuable of our diagnostic aids; but it should be an assistant, not a master.

The information obtained from blood analyses, when these are conscientiously and competently performed, is valuable; but their availability does not excuse neglect of strict dietetic control and of the indications obtained by correlating a known intake with the results of quantitative urinalysis. Blood taking is more impressive than diet control and urine taking; but blood analysis for nitrogenous constituents is more capricious and in most cases is not more informative. Blood taking is often very disagreeable to the patient, even with a skillful operator.

There is more justifiable laboratory work than most hospitals can afford to do. Let us limit the demands on the laboratory to this really useful work, and let us use it intelligently.

PENALIZING EDUCATION

IT was, at one time, not unusual to find in publications of a certain class, advertisements of the following type:

> Wanted.—College graduate as governess to teach three children the usual subjects, also French, German, and music; and to help in the house. No salary, but the advantages of a Christian home.

Such advertisements are rare nowadays, though the following, culled from the columns of a New York contemporary, seems to carry an echo of those bygone days:

> Religious organization wants stenographer . . . looking for high grade, trustworthy person who considers . . . high character of employment more desirable than temporary wage profiteering.

Recently, an advertisement for a pathologist

has appeared in the medical press, inserted by a first class state medical school. The highest possible qualifications were demanded, graduates of Johns Hopkins, of Harvard, or of the school advertising, only would be considered. Experience of teaching and of laboratory practice was called for. A man who could measure up to the specification would be not less than thirty years of age. The salary offered was $1,600 per annum. Less than the present average earnings of a bricklayer's laborer.

We shall be told that the enormous advantage of association with distinguished colleagues outweighs the paltriness of the remuneration. "No salary but the advantages of a Christian home!" Doubtless our attention will be drawn to the "prospects."

A bull stood on an arid mountain overlooking a verdant but distant plain. "Splendid prospect," he said, "but damn little grass."

The man who accepts this post either decides on celibacy at his best age, which is anti-social, or he is moneyed. In the latter case, the service of the state is reserved to, and the money of the people is being employed for the advantage of a privileged class.

At the present time, to preach education as a means to material success, is to deceive our hearers. Brains are paid for but *not education.* Real education is a drawback.

If you want your sons to make a material success in life, let them leave school in the grades and start as newsboys. Then, in early adult life, they may be in a position to employ highly educated men to eke out their own slender erudition, at salaries less than they dare offer a second rate chauffeur.

CARDIAC AILMENTS A PREVALENT CAUSE OF DEATH

CARDIAC ailments are far more prevalent than is generally suspected, while ignorance of this fact is a matter of surprise, since the danger from this class of maladies is fully understood, according to a pamphlet issued by the Association for the Prevention and Relief of Heart Disease.

An official report of the health department of the Association shows that 10,682 deaths in New York City alone in a single year were directly due to organic disease of the heart, while in the same period tuberculosis, in all its forms, caused 9,622 deaths and cancer but 4,702.

The Association declares that not less than 25,000 public school pupils of New York City have permanently damaged hearts while many more suffer from other diseases which are liable, unless controlled, to bring about the same result. Adults suffer for years from heart disease, mistaking their symptoms for those of indigestion or other stomach troubles, and wonder why their sufferings do not yield to home remedies.

The Association in its pamphlet asserts that the prevention of heart disease presents both medical and social problems, but it urges the prompt removal of diseased tonsils and adenoids and the immediate care of decayed teeth, as the most effective preventive against infection with rheumatism, which is cited as an infectious disease more frequently affecting the heart.

Poisons of alcohol, tobacco, tea, and coffee are mentioned as "playing a definite rôle" in degenerate diseases of the heart.

Dr. Lewis A. Conner is president of the Association, and Ray Morris, the treasurer, while among the governors, who number many lay members, are Dr. Alexander Lambert, Dr. Haven Emerson, Dr. John W. Brannan, and Dr. S. Josephine Baker.

The Association is now engaged in furthering the establishment of dispensary classes for workingmen with crippled hearts in the many city hospitals, and also seeks the opening of more convalescent homes to patients of milder type, and the founding of institutions for the permanent care of permanent invalids from the same cause.

SCIENCE AN ESSENTIAL COMMODITY

THE general public of this day wants more from the medical profession than was demanded by the public of yesterday. Health officers have educated their communities to the need of better living conditions, improved sanitation in cities, and new standards of hygiene. Their colleagues in private practice and in the hospitals have brought to thousands of families a better knowledge of the service which the physician and surgeon can perform for society. Industrial physicians have established a firm and lasting working acquaintance with employers by demonstrating to them the direct benefits that come from utilizing medical science for business ends.

Physicians see in these manifestations of public interest a greatly increased demand for their skill. It is the law of supply and demand in operation. The physician has created new demands and it becomes his business to supply these demands. How shall the medical profession meet these needs that only medical science can satisfy?

Here are circumstances which compel the medical profession to undertake the task of reducing the recondite findings of research to simple state-

ments that will find a broad application in all health fields. It may require a hundred years of observation to formulate a physical law, but once formulated, it should be immediately put to work in the service of science and mankind. The findings of the laboratory are not for the edification of the initiated, but are subject to translation into terms of physical betterment for the masses.

The time is right for such interpretation to the people. The physician is free to admit that his highly specialized service, without better organization, is not available to the masses. The employer begins to see the relationship between high pressure methods, bad working conditions, and reduction in output, time loss, and the expensive labor turnover. The employment manager senses the need of a psychic as well as a physical evaluation of his men. Sporadic health education and the piecemeal efforts of uncoordinated health agencies have so far enlightened the mass of the people that they begin to demand health for themselves, and a place in the sun for their children. They are no longer content with unremitting, unrewarded toil, and begin to react in various ways from the repressions they have suffered.

The interest is keen and universal. All that is needed is an interpretation of science into the language of the people; a survey of the general situation; and a coordination of existing health agencies so that duplication of efforts and costs will be eliminated, and the entire field covered.

The difficulties of such an undertaking are not insurmountable. The problem exists. Every one is groping. The physician needs a more universal contact. The employer needs a more comprehensive view of the whole industrial situation. The manager needs a sympathetic understanding as well as trade tests. The worker needs more than a pay envelope.

In other words, there needs to be a universal understanding and a widespread application of modern science to the necessities of real life. Nothing is detached or isolated. The physician must not lean to research to such a degree that the problem interests him more than the patient. On the other hand, interest in special directions is all gain if scientists, after each excursion into their several fields, rejoin one another on a common ground to report and reckon progress. Thus will the essential unity of all the sciences be appreciated and mankind be made the beneficiaries of the cumulative stores of knowledge. "Knowledge is more than power; it is the condition for growth." The essential thing, therefore, is a constant and complete interchange of ideas, mutual need met by mutual service.

TO DIRECT RED CROSS HEALTH SERVICE DEPARTMENT

Dr. Erwin A. Peterson of Cleveland, Ohio, who has been named director of the newly-created special health department of the American Red Cross to direct certain phases of the organization's health conservation program.

DR. ERWIN ALBERT PETERSON, recently appointed director of the Health Service Department of the American Red Cross, is a graduate of Ohio Wesleyan University and of the Medical Department of Western Reserve University of Cleveland. He has had an extensive experience as an educator, a social worker, and a health executive, having been head worker of Goodrich Social Settlement for several years, and a teacher and director of the School Health Department of the Cleveland public schools, where he built up one of the strongest departments of the kind in the country. Dr. Peterson served as major with the American Red Cross Commission on Tuberculosis to Italy, during the war, and directed the Educational Hygiene Department. He is intimately acquainted with the different types of communities with which he will have to work, as he was born on a farm, spent his later boyhood in a town of less than 10,000 inhabitants, and after leaving college lived in a city. Dr. Peterson brings to his work a technical training supplemented by a very valuable social and educational experience. He is now located at National Headquarters, American Red Cross, Washington, D. C. The plan of the work which he is to undertake calls for cooperation with other existing health promotion and disease prevention organizations throughout the United States, the Red Cross acting alone where no other health agency exists, in an effort to reduce the high mortality due to preventable disease, and to improve general health conditions. Public health nurses will be assigned to many small communities.

REHABILITATION IN ITS RELATION TO THE PHYSICIAN

By A. C. BURNHAM, M.D., New York

THE Vocational Rehabilitation Act as amended by the Act of July 11, 1919, provides, "that every person enlisted, enrolled, drafted, inducted, or appointed into the military or naval forces of the United States, who since April 7, 1917, has resigned or has been discharged or furloughed therefrom under honorable condition, having a disability incurred, increased, or aggravated while a member of such force, or later develops a disability traceable, in the opinion of the Board, to services with such forces, and who in the opinion of the Federal Board for Vocational Education is in need of vocational rehabilitation to overcome the handicap of such disability, shall be furnished by the said Board, when vocational rehabilitation is feasible, such course of vocational rehabilitation as the Board shall prescribe and provide."

SOLDIER AND CIVILIAN

Medical service under the Vocational Rehabilitation Act provides for every eligible sick or injured soldier the sort of care his case calls for, and such re-training as restores him a functioning member of society.

The machinery of medical organization under this service has been developed to reach every disabled man, and care for him till he is self-sufficient and self-sustaining.

Is it visionary to hope that the same standard of scientific care may some day be available for the average citizen?

Application Depends on Physician

The work now being undertaken by the Board is interesting to the physician not only from a humanitarian and social standpoint but also from a professional point of view, because so much of the practical application of the Act is dependent upon the physical examination of the applicant, and upon the opinion of the medical examiner as to the advisability and feasibility of any suggested course of vocational rehabilitation.

How does the United States Government decide whether the disabled soldier or sailor or marine has or has not a sufficient degree of disability to entitle him to vocational training? How does it decide whether or not the training is suitable for the individual case? How does it decide whether an injured soldier is physically able to continue training after it is once begun?

If you were in the military forces of the United States and were wounded in the Argonne, or if you were struck by a truck at Brest, or if you developed tuberculosis at any Army camp and never got abroad, and if, as result of your injury or disease, you are handicapped in the pursuit of your ordinary occupation, you may be entitled to vocational training by the Federal Board.

Soldiers are kept in the Army until their physical condition is practically stationary, until the wound is healed, and the disability shows no further signs of improvement; or until the disease, if it be rheumatism or tuberculosis or what not, has reached a stationary stage. He is then discharged from the Army on what is known as a "C.D.D.," a Certificate of Disability for Discharge. This certificate of disability states the degree of disability, which is the preliminary information upon which the allowance for War Risk Insurance is based. In this, as in all the steps of rehabilitation, the procedure for the sailor or marine is practically the same as for the discharged soldier.

To Reach Every Disabled Man

The man is returned to his home and if he happens not to have seen the camp or hospital representative he then takes up the question of training with the local representative of the Division of Rehabilitation, Federal Board for Vocational Education, in one of the fourteen districts of the country. The Board is anxious to get in touch with every disabled man. This has been done largely by representatives at the hospitals and camps previous to discharge, and for later cases through the official records, especially those of the Bureau of War Risk Insurance and the Adjutant General's office at Washington. If the man has a self-evident disability, the Board makes the attempt to get in touch with him if they have any possible means of locating his whereabouts. Amputation, partial blindness, and all serious cases are passed upon with the least possible delay. Training is often begun within a few days.

The ex-service man has had the best medical and surgical intellect of the country interested

in his recovery. He has been under the care of specialists, the best obtainable in either military or civilian medicine. Many prominent surgeons are being retained in the Army and Navy largely for the care of the wounded soldier. He has had privileges of x-ray and laboratory facilities to an extent not available to the average civilian. He has received his Army pay and allowance while he was under treatment, previous to discharge.

For the purposes of administration the Division of Rehabilitation has divided the country into various districts. The New York District, with offices on the seventh floor at 469 Fifth Avenue, has charge of all the discharged men in the states of New York, New Jersey, and Connecticut. It is numerically the largest district in the country.

Let us suppose that the soldier has applied for training at the District Office. He is first seen by the vocational advisor who talks the matter over thoroughly with him and decides tentatively on a course of training which is agreeable and suitable to the man and at the same time possible of execution. Training is suggested as far as possible along lines in keeping with his former experience and education.

The Classification of Handicaps

Here again the medical profession is called upon. The man is sent with all available records to the District Medical Officer or one of his assistants. The physician examines him carefully and gives his opinion as to whether the condition is a major, minor, or a negligible handicap. This is a very important decision because the character of the training depends on whether the case is considered as major or minor.

The instructions issued by the Federal Board on this point are as follows:

(1) *Major Handicap.*—This classification includes cases in which, from the point of view of the entry in question, the disability will be a real and permanent handicap in the occupation such as to affect employability and earning power.

(2) *Minor Handicap.*—This includes cases in which, from the point of view of the entry in question, the disability involves some inconvenience that does not interfere in any real way with the employability or earning power and that frequently may become negligible after a brief experience in the vocation.

(3) *Negligible Handicap.*—This includes cases in which from the point of view of the entry in question, the disability may be disregarded in considering the man's employability and earning power.

In some cases the question of handicap presents a difficult problem. Especially is this so of those who complain of disability with indefinite or ill defined symptoms. In such cases the District Medical Officer may send the man to a specialist for consultation, to a radiographer for an x-ray, or to a laboratory for a special analysis. Here the physician has at his command all the methods required by modern scientific medicine for the diagnosis of disease. For example, a man complains of weakness in his hand following a gunshot wound of the arm. A neurological examination shows that he has a partial paralysis of one of the nerves of the arm and that his disability is probably permanent. Such a man will be classed as a "major handicap." Another complains of pain in the elbow when the elbow is bent, following an old fracture. An x-ray of the elbow shows a small spicule of bone projecting into the joint. Operation is not considered advisable and the man is given a "major handicap, probably permanent." The examination, involving as it does one or more specialties, is such as cannot be secured by the average civilian because of the expense.

Some men are found who are not fit for training. They show a recurrence of their war disability or a complication of their injury after leaving the Army. What can be done for them?

Medical Care is Available

If the condition is mild it may be treated by the United States Public Health Service which undertakes the care of illness of this type. They have a number of hospitals for the care of these patients, among others the Marine Hospital on Staten Island and what was formerly the Polyclinic Hospital on West Fiftieth Street. Once more the best of medical treatment is available. The medical service is augmented by the employment of local specialists. When the patient is cured, he applies again to the district office of the Federal Board for Vocational Education for training.

After the man is passed upon by the medical officer and the vocational office, his papers must be reviewed by the District Case Board and finally approved by the Federal Board in Washington. When approval is received, his training is started. To obviate delay, representatives from the central office at Washington have recently been placed in the district office.

Major handicaps entitle the man to training and eighty dollars monthly. When there are dependents, an additional allowance is made. Minor handicaps entitle the man to a period of training during which time he continues to receive his allowance from War Risk Insurance. In case of

a negligible handicap the attempt is made to place the man in a position without training.

However, the physician and the disabled soldier have not yet parted company. During the course of training the man may break down or may find that the work is unsuited to one with a physical handicap. The doctor again examines him and may recommend hospital treatment, or may advise a change to another vocation for which he is presumably better fitted.

During the training the man is supposed to be treated by his own physician for intercurrent disease if it occurs. However, through the Red Cross, medical attention is available not only for him but for his family as well. A large number of men have been cared for through this agency and a number of men sent to the country for periods of convalescence.

Personal Equation in Injury Cases

There is a considerable human interest problem in the examination. There may be seen some of the terrible results of war, met with a spirit of bravery and heroism worthy of the cause. Some men appear determined to belittle their disability and have to be argued into accepting training. Such men succeed with a small amount of help and guidance. On the other hand, cases are seen in which a simple injury with no apparent disability has so unsettled the soldier's mind that he is unable to undertake any form of vocational education. These latter are the hardest cases to deal with, the men being unsettled and not to be depended upon. It is hoped that in time they will find themselves and become useful citizens.

The following three cases are typical:

F. O. B., age 24, Sergeant, Field Artillery. Irish parentage. Enlisted April 19, 1917. Discharged October 7, 1919. *Diagnosis*—Old scar following mastoid operation, left side. In hospital nine months. Discharged from hospital October 7, 1919. *Disability*: Deafness, left ear. *Previous Occupation*: Student, self-supporting. Unable to continue course for lack of funds. In this case the handicap is considered as 25 per cent. If this man is allowed to complete his course in electrical engineering, he will be able to overcome his handicap. Recommended for course in Massachusetts Institute of Technology.

E. W., age 24. Serbian parentage. Enlisted in Infantry December, 1917. Wounded July, 1918. In United States Army hospitals eleven months. Discharged June, 1919. War Risk Bureau gives disability as 75 per cent. *Previous occupation:* Laborer. Examination shows multiple gunshot wounds completely healed. Complete blindness, right eye, following wound of temple. Deformity of right hand following G.S.W. Is unable to use hand for finer movements, but has strong grip and will be able to do heavy work. New occupation advised: vulcanizing. This man will be sent to a trade school to learn vulcanizing. As a skilled worker he should receive more pay than previously and be able to overcome his handicap. As a laborer he would be a charge to the community.

R. S. G., age 26. American. First-class seaman. Enlisted November, 1917. Served as armed guard on commercial liner. Discharged January, 1919. *Previous occupation:* Machinist's helper. *Diagnosis* (February, 1919): Nephritis, chronic parenchymatous. Disability complete; unable to perform any work. Referred to Marine Hospital, Staten Island, for treatment. October 8, 1919: Man has been in hospital for nearly eight months. Returns anxious to go to work. Examination shows that he is still suffering from nephritis and able to do only very light work. If this man does hard work his trouble will be aggravated and he will be a charge on the community. He should be sent away where he will have the opportunity to do light work and where he will be under medical supervision.

CONGRESS ON INTERNAL MEDICINE

The American Congress of Internal Medicine will meet in conjunction with the American College of Physicians in Chicago, February 23 to 28. The sessions will include daily clinics and laboratory demonstrations in hospitals and teaching institutions, and evening meetings, one of which will embrace the Fourth Annual Convention of the American Congress of Internal Medicine.

UNIFIED MEDICAL SERVICE IN ENGLAND

The growing possibilities of improvement in personal and social welfare depend very largely upon the extent to which each practitioner becomes a medical officer of health in the range of his own practice, says Sir Arthur Newsholme in the Reconstruction number for January, of *The Survey*. By socialization of medicine, he means rendering available to every member of the community, irrespective of any necessary relation to the ordinary conditions of individual payment, all of the potentialities of preventive and curative medicine.

He gives a short historical account of the claims of preventive medicine in saving and prolonging human life. Hospitals offer a partial solution in reducing the possibility of massive infections from tuberculosis, for instance. The most significant field in which preventable disease continues and which promises immediate and favorable returns is the systematic improvement of the sanitary environment of maternity and childhood. A concise statement is made of the personnel and organization of the whole- or part-time medical service rendered by the medical profession in England to the Government, which now constitutes a nearly completely unified state medical service.

Complete service, adequate to the needs of the community, he considers must grow not by legislation but as the result of steady advance. The outstanding needs are: (1) The provision of hospital beds; (2) the provision of gratuitous medical services for maternity and infant consultations, eye, throat, skin and venereal disease, tuberculosis, and x-ray service; and (3) the provision of a complete nursing service, available under the easiest possible conditions.

The hospital would thus become a center from which the community work would radiate in the practice of preventive medicine in its widest sense, and it is not beyond the range of human ingenuity to provide schemes for district medical officers (health and clinical), adequately trained in public health work, and linked up closely with the hospital and dispensary unity for their area. "Sound health is our greatest personal and national asset, and disease is more expensive than health."

THE SANITARIAN'S DEFINITION OF A LIVING WAGE

By DONALD B. ARMSTRONG, M.D., Assistant Secretary, National Tuberculosis Association; Executive Officer, Framingham Community Health and Tuberculosis Demonstration, Framingham, Mass.*

WHAT constitutes "an adequate family income"? Never before has so much consideration been given to this question and never has there been so widespread and insistent a demand for an economic adjustment which will effect an adequate income for the great mass of citizens.

It is not the purpose of this paper to deal with the dollars and cents considerations of this problem. Others, with more knowledge and greater experience, are studying the practical side of the question. We now have available the recent valuable work of Commissioner Meeker, one of the nation's foremost authorities on this subject.

Presumably, those who are giving attention to the question of a theoretically adequate family income, a "living wage," include in their considerations the essentials for disease prevention and health maintenance. We shall endeavor in this paper to try to find out, not so much what these essentials cost nor so much what proportion of a total income must be spent for health essentials, as what the essentials *are*.

Problem Has Dual Aspect

To meet present urgent income needs many old established formulae, and many new panaceas, are being advocated. From the point of view of solution, the problem seems to have a dual aspect, forcing recognition of two main factors: (1) the need for more money; (2) and perhaps as an alternative, the need for lessened disease hazard.

It may perhaps be worth while to mention a few of the more conspicuous devices that have been experimented with to meet these needs. We have, for instance, as measures to increase and standardize income:

(1) *Minimum wage legislation.*—So far as this country is concerned, the first minimum wage legislation was enacted in 1912, and we now have legislation of this character, aimed at the protection of women and children, in thirteen states. Coincident with this legislation have come efforts to determine the minimum essential family income. For instance, in December of 1917 the Bureau of Municipal Research of Philadelphia estimated that $1,200 was necessary for the maintenance of a family of two adults and three children. More recent estimates, based on subsequent increases in living costs, place the minimum at $1,500, a figure recently set by students of the problem in Cleveland, Chicago, and elsewhere.

(2) *Wage boards.*—Out of the minimum wage agitation have come official wage boards in many of our states. The wage board type of legislation has the advantage of greater flexibility. A bureau or commission is created, and wage boards are formed for the important occupations. These boards have been endeavoring to set a minimum rate of wage that shall be "sufficient to cover the necessary cost of proper living."

Independent Relief Measures

Certain industries, acting independently, have also endeavored to meet the wage problem in somewhat this way, specifically by a current adjustment of wages to the cost of living, according to a more or less complicated formula. For instance, this plan has been adopted by the Franklin Motor Company. The danger in this method seems to be that of inflexibility. Unless carefully devised, the rigidity of the scheme makes it difficult to effect a greater relative increase in wages at the lower end of the scale, where the increase is most needed.

On the other hand, as measures to lessen the stress and hazard of industry and thereby decrease the sickness drain upon family incomes, there may be mentioned a number of movements, such as the "one day of rest in seven" agitation, the "eight hour day" movement, and the expansion of medical and social welfare work in industry. Conspicuous in this group of measures

THE WILL TO HEALTH

Disease is not, as unregulated humanitarians would have us believe, necessarily a result of economic conditions, nor does a living wage, even in connection with adequate health machinery, insure an appreciation of health values.

A living wage does not assure healthy habits, for the rich and the poor alike fail to practise personal hygiene.

To insure that the worker lives up to his health knowledge, the standard of living must be raised to a good working morale. Self-expression, the instinct for workmanship, enthusiasm for the job, are presupposed before we can hope to arouse in the workman an effectual will to health.

*Read before Forty-Seventh Annual Meeting of the American Public Health Association, New Orleans, October 27-30, 1919. Published through the courtesy of the American Journal of Public Health.

is the tendency to experiment with various forms of sickness insurance, one of the most effective of which is the mutual employees benefit association, which puts the burden of increased illness in part at least upon the employees, through higher insurance rates. All of these movements, aside from their social and medical value and significance, do undoubtedly tend, indirectly at least, to bridge the gap between inadequate income and essential needs.

This is by no means a complete list of the movements in this field. It is simply a more or less haphazard selection of the devices employed to meet the problem, and is in that sense only a summary introduction to our subject.

A Question of Interrelations

From the point of view of the sanitarian it is perhaps more logical and useful to give primary consideration to certain more general questions. Certainly from his point of view it is desirable to determine what are the essentials of hygienic living, and what constitutes from this aspect a "living wage." It is perhaps necessary to go even further back, and to define with greater care than is ordinarily the case the fundamental terms in the present discussion.

What, for instance, is "living"? What is the relation of "living" to health? Is it not obvious that the definition of a "living wage" must depend on the definition of "living"?

Now, the relation of health to living presents two complementary aspects. It has both a negative and a positive phase. It is both preventive and creative. We should demand for every family the means to prevent disease, that is one consideration. We should also demand for every family the means to create health for that family,—this is a second and larger consideration. This latter consideration means the opportunity for health, mental and physical,—really the opportunity for happiness.

Obviously, "living" means more than existing and to live adequately demands more of the imagination, and also more of the pocket book, than to exist. "It is not life we love, but living." To live is to be free from the burden of present poverty and the fear of future want, and to be able to enjoy present good.

Disease by Economic Groups

In the relation of income to illness we ought also to refer to certain fallacies, or at least partial truths, which need to be recognized.

Undoubtedly the most distressing cases of poverty are found in association with protracted disease, such as tuberculosis. Consequently tuberculosis workers are perhaps more than others impressed with the cause and effect relationship that apparently exists between disease and poverty, or poverty and disease. It is frequently stated that it will be impossible to stamp out tuberculosis so long as people live as they do, in extreme poverty, with poor food, inadequate housing, and in squalor, filth, and congestion. This is certainly more or less true, and because of the relationship of poverty to disease the income is a fundamental consideration. Yet it is not the whole consideration, as must be evident from certain striking findings derived from the tuberculosis field itself. A too rigid assumption of the theory of the economic cause of disease, introduces certain fallacies and premature assumptions.

In a general way it may perhaps be safely stated that the cause of disease depends upon three main factors: (1) the environment, which includes hygienic surroundings, the possibilities of contact, working conditions, income, and such factors as economic and social adjustment; (2) race habits; and (3) race stock.

This last factor, namely, race stock, seems to be of greater importance than is ordinarily supposed; though it is a factor that the environmentalist, closely concerned as he is with the immediate and practical problems of human relationship, tends very easily to lose sight of. By way of illustration of the importance of other than direct environmental factors, there may be offered the following points, from the records of the Framingham Community Health and Tuberculosis Demonstration:

(1) Disease incidence (general morbidity and tuberculosis) by community districts, classified on an economic basis.

One of the activities of the Framingham Community Health and Tuberculosis Demonstration has been the examination of as large a section section of the population as could be reached. One of the reasons why Framingham was selected for this work was because it offered exceptional opportunities for the classification of disease incidence according to economic groups, the community being naturally divided, in a fairly clear cut fashion, into several sections manifesting distinct and contrasting characteristics from the point of view of social and economic status.

The organization in Framingham has outlined the community for this purpose into seven districts. The general status of these districts may be most brifly summarized as follows:

District I.—Lower middle class: individual workers; Irish and Irish-American race stock; hygienic conditions fair.

District II.—Middle and upper class: American; hygienic conditions good.

District III.—Industrial workers: Irish-American and a few foreign born; hygienic conditions fair to poor.

District IV.—Industrial workers: foreign born Italians; hygienic conditions poor.

District V.—Upper class: Americans; hygienic conditions good.

District VI.—Lower middle class: industrial workers, Irish-American and French-Canadian stock; hygienic conditions poor.

District VII.—Rural: American stock; hygienic conditions good.

On the basis of these districts the following distribution of disease as discovered in the examinations will be of interest.

Total Morbidity

For the community as a whole, with a definition of illness that included all types of disease and defect of a serious or minor character requiring medical or dental advice or treatment, the incidence rate was 77 per cent of the total number examined. For this total factor the districts were classified as follows: District I, 77 per cent; District II, 68 per cent; District III, 79 per cent; District IV, 79 per cent; District V, 77 per cent; District VI, 83 per cent; District VIA, 72 per cent. The districts if arranged in order of increasing disease incidence would fall as follows: II, VIA, V, I, III, IV, and VI. It will be noted that the districts with the best hygienic and economic conditions have the lowest rates, the middle class District II, the superior rural section, and the high class Section V taking first place. The foreign born section and the industrial sections have the highest disease rates.

From this evidence, as far as it goes, we may conclude that general morbidity seems to show an increasing incidence as economic welfare decreases. To that extent the Framingham evidence lends support to the general assumption that sickness may be closely correlated with income and economic welfare.

The Incidence of Tuberculosis

On the other hand, when we come to the study of tuberculosis incidence, it is found that different conditions apparently prevail. For the group as a whole the incidence of tuberculosis, including active and arrested cases, was 2.15 per cent. The district rates were as follows: District I, 2.76 per cent; District II, 2.74 per cent; District III, 1.65 per cent; District IV, 1.54 per cent; District V, 2.66 per cent; District VI, 2.60 per cent; District VIA, 2.22 per cent. For tuberculosis, the districts arrange themselves in order of increasing tuberculosis incidence as follows: IV, III, VIA, VI, V, II, and I. Here we find the section with the poorest hygienic conditions and the most congestion, but with a predominant Italian race stock, presenting the lowest rate! Further, the section with the best general residential conditions in Framingham (II) presents next to the highest rate. The highest rate of all is found in a district with fair economic and hygienic conditions, but with a heavy mixture of Irish race stock. From these findings it would appear that, as far as tuberculosis is concerned, we must look for determining factors other than economic and sanitary conditions. It is apparently true that race stock, under these circumstances, outweighs all other factors.

Tuberculosis Incidence by Race Stock

In Framingham the numbers examined for most of the nationalities reached were too small to be of any general significance. This, however, was not true for the three most prominent nationalities; namely, American, Italian, and Irish. Bearing in mind that the incidence for the group examined as a whole was 2.15 per cent, it is of interest to know that the rates for these three nationality groups were as follows: American, 2.58 per cent; Italian, 48 per cent; Irish, 4.85 per cent. This great contrast in tuberculosis incidence when racial groups are compared seems to bear out the assumption made previously that the race stock factor may at times at least assume an importance considerably greater than the most clamorous hygienic and economic conditions. It will be remembered that the Italians living in District IV are among the poorest class in the community, and without question are surrounded by the worst hygienic conditions. Yet they show only about one-tenth as much tuberculosis as their more fortunate, hygienically and economically, Irish brothers!

Tuberculosis Incidence by Income

In the Framingham work, the families in which tuberculosis occurred when classified according to income groups showed relative rates of family infection as follows: Under $1,200, 4.3 per cent; $1,200 to $1,800, 5.1 per cent; $1,800 and over, 2.7 per cent; unknown income, 7.2 per cent. In discussing these findings, Framingham Monograph No. 4 on the "Medical Examination Campaign" may be quoted as follows:

"While the figures here are perhaps too small to be used as a basis for final conclusions, there is little to indicate that the economic factor is a predominating and absolutely determining one in

the incidence of tuberculosis. The results as discussed previously would indicate a similar discrepancy between these findings and the ordinarily accepted view regarding the relationship of income to tuberculosis incidence. As was pointed out, the poorest section of Framingham, with Italian race stock, had the lowest rate, while one of the highest rates was found in the best residential section of the community. Apparently other, perhaps less tangible, factors are to be looked for."

Aside from the fallacy in popular conception which these findings would apparently disclose, what is the significance of this, from the point of view of family income? Does it not mean simply that it costs more for Irish families to *live* than it does for Italians? May it not be that we must grade our income groups to some extent at least on the basis of race habits and race stock? Certainly we cannot ignore these factors when planning a "living wage."

As a matter of fact while the most ordinary environmental factors appear to be purchasable for the same amount of money for everybody, in reality they are not so. The negro in the North cannot, for the same amount of money as the white, buy as good medical, dental, and obstetrical care, for the reason that he labors under race and social disabilities and lacks the facilities of group organization. If the Italian can stand more hardships than the Irish and still be free from disease and able to promote health, this simply means, for the Irish, that they will have to spend more money than the Italians to get equally effective (for them) environmental conditions. This means that a living wage for one race is not necessarily a living wage for another.

In the consideration of the vigor and vitality of a people, all elements, material, mental, and social need to be considered.

The greatest hope and at the same time the greatest hindrance in any health program is in the attitude of the people themselves.

We must admit that we cannot put over "health for health's sake," but must fall back on emotional appeal to make men desire to really live, and to value health as a factor essential to the adventure of life.

We succeeded in making men eager to be fit to fight; how can we make them eager to work and live?

Not forgetting these differential factors, what are the things which all families must have if they are to live adequately and safely from the point of view of the sanitarian? As stated previously, this problem has a negative and a positive phase, a preventive and creative aspect. We may classify the essentials of adequate sanitary living as follows:

Every family should have at its command facilities and conditions that will ward off unnecessary and preventable disease. These essentials are as follows:

(a) *Proper Physical Environment.*—Because communicable disease is largely a matter of human contact, the sanitarian should insist on proper housing, adequate equipment for personal cleanliness, the elimination of congestion, sufficient light, heat, and ventilation.

(b) *Essential Living Materials.*—These would include such items as clothing, food, and fuel. The sanitarian must also here take into consideration the educational facilities available in the community regarding the use of these materials. A living wage for a family properly instructed regarding the selection and use of food, for instance, may not be a living wage for the family that does not have the advantages of the educational opportunities involved herein.

(c) *Professional Care.*—The living wage must include funds sufficient for medical and dental care, nursing, and essential hospitalization.

(d) *Anti-Stress Factors.*—From another point of view, it is essential for any family, if disease is to be prevented, that they be able to take advantage of the best working conditions. This cannot be done if the income is inadequate; if the individuals are, therefore, subject to long working hours, inadequate rest, excessive over-time, and other elements of industrial strain. This is perhaps of particular importance in the field of tuberculosis. Recent work in Framingham and elsewhere has indicated the existence of a large group of arrested tuberculosis case, most of whom are working and *can* work under decent economic conditions, and if not exposed to excessive industrial stress. As a matter of fact, whether we belong in the arrested tuberculosis group or not, this applies to most of us, and we must have an income which makes possible the avoidance of excessive strain if a breakdown is to be warded off.

It is helpful to look at the wage of the worker as something which he purchases with time and with effort, either mental or physical. A man with a great deal of over-time might secure an income as a laborer of $50 to $75 a week, but the probability would be that he actually could not afford to spend his labor for that wage. Conse-

quently, no matter how much he "earned" he would not be receiving a living wage, for living would be impossible. Similarly the man who works at a hazardous trade and who, say through lead poisoning, acquires a permanent physical handicap in early maturity, is spending more for his wage than he can afford, no matter how much he is paid.

Means for Creating Health

On the constructive side, the family income must make possible an adequate amount of recreation, leisure, and education, if real healthful living is to be possible. The worker must have these things if he is to have happiness. Happiness is largely ignored because it is imponderable, but the worker must be able to buy it. Two things are essential to his happiness. He must have an adequate income to purchase leisure, recreation, and education, and he must have an occupation which is at least tolerable; if possible, joyous. This the miner and the lumber camp worker, for instance, working in isolated and poorly equipped environments, cannot do. Under these conditions a discussion of a living wage is out of the question. No money wage is sufficient to be called a living wage if the worker must live in a way that precludes his purchase of happiness.

Probably the sanitarian more than anyone else is conscious of the fact that the great majority of families live in a vicious circle. The circle is made up of alternating segments which might be labelled "poor wages," "poor health," "poor wages," " poor health," and so on. The simile of the circle is somewhat misleading, for this turns out to be more frequently a descending spiral into the regions of destitution. The problem for the sanitarian is how to find a place to break into that circle, and to put these families on the ascending stair in which the steps are "good wages," and "good health."

It is of course impossible to put these living essentials,—the things that must be secured for the average family before it can be put on the road to economic freedom, health, and happiness, —into money terms. It is, however, extremely important to realize the range of these elements and to keep them in mind when working, legislating, and agitating for an adequate income.

It must be evident that a higher standard of living must be established. A higher conception of living standards would in itself presumably do much to accelerate wage increases and to retard wage reduction. If the worker himself knew the value of happiness, and the necessity for leisure, recreation, and education, as prerequisites to happiness, this in itself would be perhaps the greatest stimulus to a living wage. All of us, including the worker, must come to realize that the definition of a living wage depends wholly on the definition of living; that understood, the wage will tend to take care of itself.

How Should Money Be Spent?

We cannot, however, face all of the realities in this situation if we do not admit that right here we are up against another and most serious problem. The problem, stated in practical terms, is how is one going to get the average worker to spend his money properly when he gets it? How can we be sure that he will really *live*, with the living wage? The trouble seems to be that a great many people are contented not to *live*.

We are willing to admit that the problems of disease prevention and health creation, for industrial workers and others are no longer in civilized communities problems of public health, but are problems of personal hygiene. Also, all are willing to admit that the rich do not practise personal hygiene. Therefore, why should the poor? Why should the living wage insure health practices? Those of us who have a living wage continue to over-work, to over-smoke, to over-drink until a recent memorable date, to lose sleep, and to take unnecessary risks of infections. Of course, there are some who would say that these things constitute living!

We must admit that an adequate income will not insure the practice of health, even if it does mean the possibility of health. Is it possible to get at this question from any other angle? Is it possible to attack this problem from the other end? If we cannot insure health by means of adequate income, can we insure an adequate income by means of health? Will an appreciation of health values result in an *effective* demand for income? It is the same staircase of "good wages," "good health," "good wages," "good health," previously discovered; but it may be that the first step is good health.

It is certain that the average person, given an adequate knowledge of personal hygiene, will not practise it. It is also certain that the average person, given a knowledge of personal hygiene, plus an adequate income, will not live according to higher health standards. Here the gain is a partial one at best.

Would an average community, given a knowledge of better health standards, provided with adequate community machinery for health, and assured of an adequate income, practise personal hygiene? It is probable that the facilities for community health would help materially, but still

it is believed that the majority would not yet be reached.

We cannot talk personal hygiene alone. The people will not listen. We must somehow supply a reason for personal hygiene while at the same time working for an adequate income to make its essentials possible.

Create a Will to Health

Who are the people in a community who practise personal hygiene? The woman who is proud of her appearance, and who is using it, consciously or unconsciously, to captivate the male, will starve herself to keep thin, will exercise when she hates it, and will practise many time-consuming and distasteful rules of hygiene. Why? Because she has an enthusiasm for her "job," and has recognized the importance of health as a factor in her success. She is not working directly for "income." If through successful marriage she gets a "living wage," and maintains it in marriage, it is incidental to her "work," just as it is inevitable if her "work" is a success.

To take another example, we have had in the American army during the war undoubtedly the greatest demonstration of personal hygiene ever made by any group of individuals. These men also had enthusiasm for their jobs. They had a *will to health* and were willing to undergo any of the drudgeries of personal hygiene and sanitation because of their intense interest in their work. The success of the venereal disease prophylaxis was a marvelous example of the efficacy of the enthusiasm of good working morale.

How does this apply to every day life, and to the problem of the living wage for the average family? We succeeded in making men eager to be fit to fight; how can we make men eager to be fit to work and live? It simply means that we must create in the average individual an enthusiasm for his work, or at least we must make possible this enthusiasm. We must give vent to the instinct for workmanship. We must show the need for fitness, and must make real the necessity for health.

This enthusiasm for the job probably depends on the proper adaptation of the man to the job and the participation of the man in the realities of his work, whether through management sharing or what not. The average worker will then see as the American soldier saw, the need for health. His working enthusiasm, and his will to health, will do more than anything else to give him the strength, virility, and above all, the reason for demanding a living wage.

The order of events must then probably be, given a normal community, the establishment, first, of a higher standard of living; then the dissemination of knowledge regarding personal hygiene; then the organization of the community to make health possible; and then the creation of happiness, enthusiasm, and morale in every day work. Only in this way can we hope for an adequate income and *its effective use.*

One Factor in Real Living

It must be remembered that we are all creatures of instinct, more or less. It must be remembered that nothing in human affairs is ever initiated or vitalized on an intellectual basis. We must find an outlet for dormant instinct, and we must supply the emotional appeal. We must admit that we cannot put over "health for health's sake." We must fall back on the creation of the will to be healthy.

From the point of view of the sanitarian a living wage is of little importance unless those who receive it are going to live well. This they are not going to do unless they secure a living wage because they have a will to live well. If this force can be gotten into the mass of men, no power on earth can prevent them from getting the fundamental pre-requisite to real living,—a living wage.

Health is after all merely one factor in real living; yet if man can be filled with an impulse to live and to serve as a more adequate medium for the expression of the vital force in the universe, he will demand, and without question obtain, a wage sufficient to purchase health, as well as any other purchasable factor essential to the adventure of life.

NATIONAL CODE FOR HEAD AND EYE PROTECTION

During the past two years there have been under consideration plans for the development of national industrial safety codes. Upon invitation extended by the Bureau of Standards, Department of Commerce, the National Committee for the Prevention of Blindness has actively cooperated in the preparation of a tentative draft of a national code for head and eye protection.

These preliminary conferences brought about the appointment of the following Committee of the American Society of Safety Engineers for the purpose of cooperating with the Federal Bureau of Standards and the American Society of Mechanical Engineers in the formulation of a national industrial safety code on head and eye protection:

G. E. Sanford, supervising engineer, all plants of General Electric Company in United States, chairman; Gordon L. Berry, field secretary, National Committee for the Prevention of Blindness; George M. Douglas, safety engineer, American Smelting & Refining Co.; George T. Fonda, safety engineer, Bethlehem Steel Company; T. P. Bradshaw, Roselle, N. J.

As the result of a meeting held November 18, 1919, recommendations were forwarded to Washington which it is hoped will meet with general approval and result in the perfection of this Code to the point where it may be suitable for general application by industrial commissions and others having legal powers, as well as by private plants and casualty insurance companies.

MEDICAL SERVICE IN HOTELS

By E. M. STATLER, President, The Hotels Statler, Inc., Buffalo, N. Y.

When the Hotel Pennsylvania, the largest hotel in the world, was opened in New York early in 1918, it is probable that no department had received more exacting attention than that centered upon the hospital. This was in line with notable developments in the welfare work which had at an earlier date been inaugurated in the Hotels Statler in Buffalo, Cleveland, Detroit, and St. Louis, and

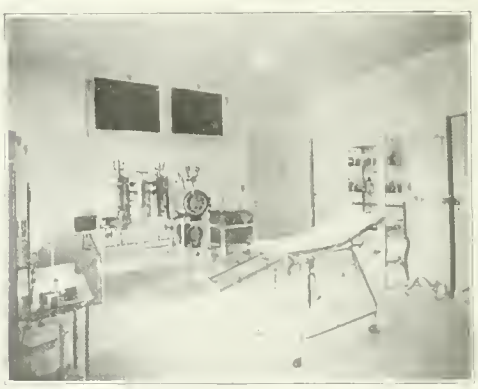
The entrance foyer to the medical department of Hotel Pennsylvania is characterized by straight lines, simplicity in furnishings and arrangement, and sanitary equipment.

The laboratory of the Hotel Pennsylvania medical department is planned for the expeditious handling of routine as well as special examinations. The most approved installation prevails throughout.

it seemed to be essential that the Hotel Pennsylvania should be provided with a fully equipped and admirably conducted hospital just as had been in successful operation in the other Hotels Statler.

In establishing these several hospitals the object has been to make health of the employees the first consideration, and to provide for them the best of medical attention whenever they needed it. There was at the same time, however, the plan to provide for the care of such guests as might need medical attention while stopping at

The most up to date mechanical appliances, complete in every detail are provided in the treatment room equipped for ear, nose and throat work.



Nothing is omitted from the operating room of the Hotel Pennsylvania that is provided for major emergency work in any first class hospital. Besides the operating room there are available an emergency ward, and x-ray room and provision for the most complete scientific records.

any of the hotels of the Statler system. Each hotel, therefore, has its special hospital, and all of them are on a par with that established at the Hotel Pennsylvania. Interest is centered at this time upon the latter because of its comparative newness.

Personnel and Equipment

The medical service in the Hotel Pennsylvania is administered by two doctors, one whole-time physician and one on call. Four trained nurses are in constant attendance. The operating room is perfect in every detail, and it compares favorably with the operating room of any hospital in the country. Besides the operating room there are an emergency ward, an x-ray room, a pathological laboratory, a record room, and a special treatment room with the necessary apparatus for eye, ear, and nose and throat work. Separate consultation rooms are provided for employees and guests.

The hospital is centrally located on the tenth floor of the hotel. It is fitted throughout in white; the walls, floors, and the operating room are lined entirely in white tile. A daily clinic is held for employees for a period of two hours, and it handles on an average of fifty to sixty cases a day. The hospital is open at all times for

inspection. Many visits are made by people interested, and it has been inspected by social welfare workers from all parts of the country.

Compensation for Care

While the guests at the hotel are required to meet the cost of such medical service as they receive, this service, with its doctors, nurses, and all its equipment provides free medical care to every employee of the hotel and to every member of the employees' families if their financial circumstances demand it.

The time and services of one trained nurse are devoted exclusively to visiting the homes of the different employees and giving such medical assistance and advice as may be deemed necessary. The whole scheme of this complete and free medical service to the employees is a part of the policy of the Statler system. Just as a satisfied guest is our best advertisement, so do we consider that a satisfied employee makes for efficient and satisfactory service.

New President of McGill

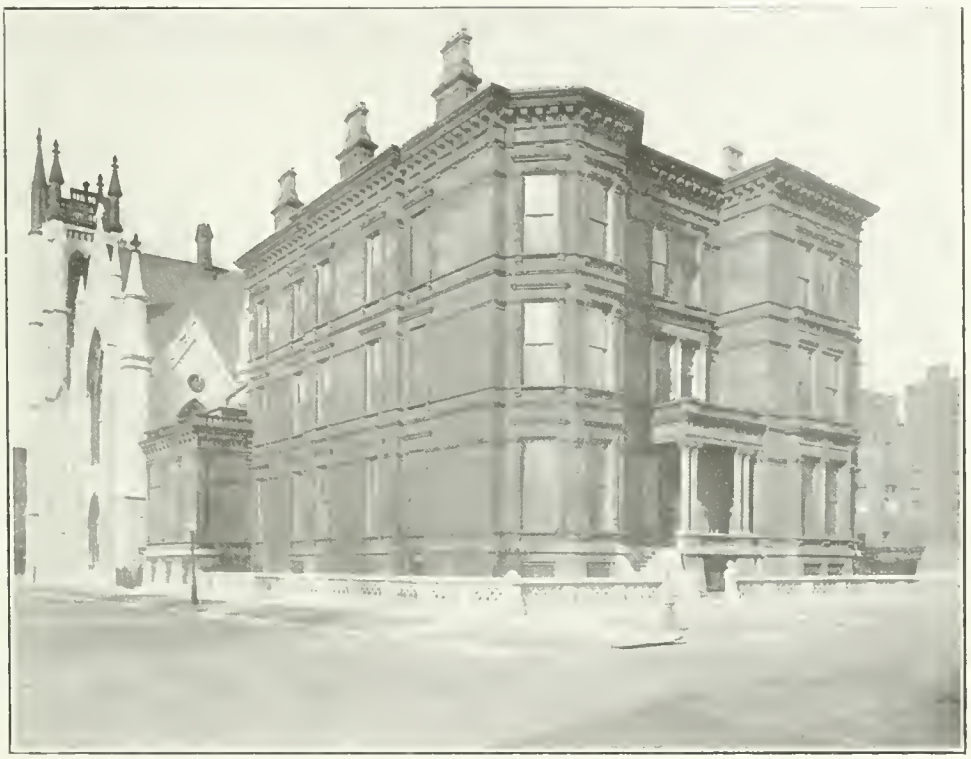
Sir Auckland C. Geddes, M.P., Montreal, who served during the war as Minister of National Service and Reconstruction, and President of the Local Government Board, formerly professor of anatomy at the Royal College of Surgeons, Ireland, has been elected principal of the McGill University.

Clinics for Practitioners

A series of medical, surgical, and special clinics is to be provided by the staff of the University Hospital, Ann Arbor, Mich., for the purpose of enabling practitioners to keep abreast of important developments in medical science. Cases having special difficulties will be demonstrated, and the schedule so arranged as to make the teaching facilities easily available to busy members of the profession.

THE HIGH COST OF LIVING

The Bureau of Labor Statistics announces that furniture and furnishings and clothing increased in price more than 139 per cent from 1913 to October, 1919. Food increased in price in that period more than 80 per cent, and housing increased 17.75 per cent, while fuel and light went more than 45 per cent over the 1913 average. The average increases for the family budget for all items amounted to 82.1 per cent. Figures are based on investigations conducted among 12,000 families in ninety-two localities.



South and west exposure of the new administrative home of the American College of Surgeons in Chicago, at Cass and Erie Streets, which was donated by patriotic citizens.

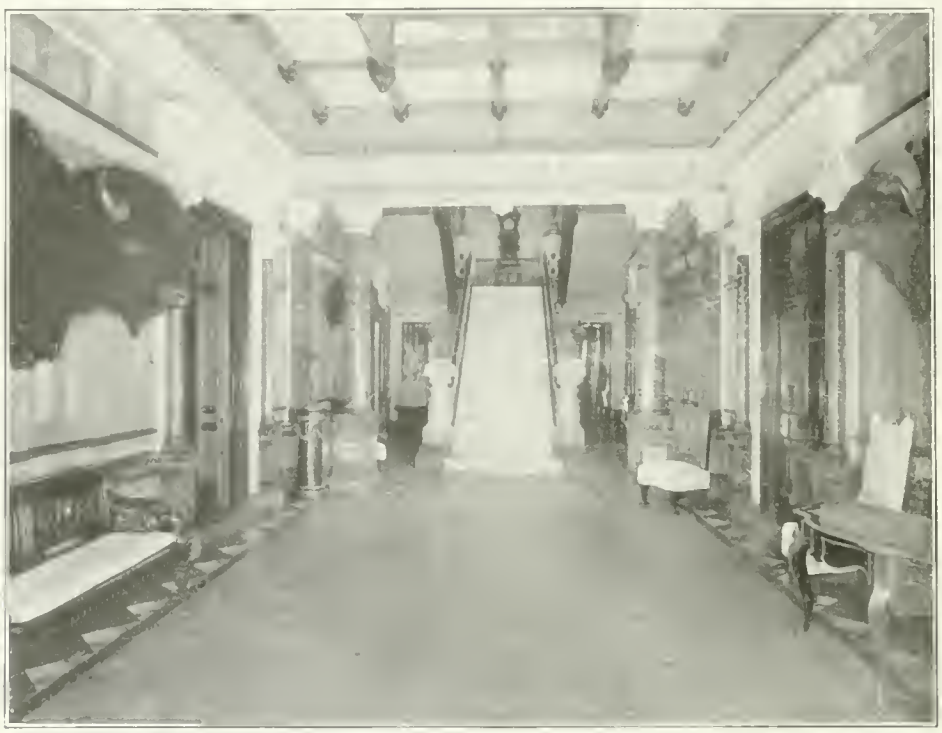
NEW ADMINISTRATIVE HOME OF AMERICAN COLLEGE OF SURGEONS

The administrative home of the American College of Surgeons has been officially located in Chicago. At the twentieth meeting the Regents of the College accepted as a gift from Chicago citizens the building and site of one of the most dignified and costly residences of the city. The selection of Chicago as the headquarters of the college was determined by a vote of the Fellows of the college.

The location of the building on the corner of Cass and Erie streets is within walking distance of the loop district, which makes it of easy access to visiting surgeons.

In construction the building is fireproof and the Bedford stone of which it is built emphasizes its Elizabethan architecture. The interior is finished entirely of hardwood and marble, the central staircase being of marble. The residence was built by Mr. S. M. Nickerson, former president of the First National Bank, Chicago, and is probably the finest building used by any medical society in the world.

The citizens of Chicago who cooperated with the Fellows of the college in making the gift include: James A. Patten, Robert F. Carr, Charles H. Wacker, S. B. Chapin, Edward F. Swift, Frank G. Logan, Edward B. Butler, J. Ogden Armour, T. E. Donnelly, William V. Kelley, William Thorne, Julius Rosenwald, Edith R. McCormick, C. H. McCormick, State Street Association, William Wrigley, Jr., William O. Goodman, Illinois Steel Company, Edward Hines Lumber Company, G. M. Reynolds, George E. Scott, Charles L. Hutchinson, Congress Hotel, Keith Spalding, R. T. Crane, Jr., M. A. Ryerson.



Lower entrance hall in the Nickerson mansion, which will form the medical hub of the world when the American College of Surgeons moves to its new quarters in Chicago.

GOVERNOR OF NEW YORK MAKES HEALTH RECOMMENDATIONS

In his inaugural address, as reported in the New York *Evening Post* of January 7, Alfred E. Smith, in urging the necessity for extending facilities for the conservation of health, said:

"I am informed that competent medical advice in the rural districts is becoming more and more difficult to obtain, owing to the tendency of physicians to concentrate in the centers of population. The country districts are in many instances practically abandoned, and earnest efforts to persuade physicians to go into these districts have been largely without result. The time has, therefore, come when there should be some plan of reorganization of health administration within the counties themselves under the supervision of the state health authorities.

"All the problems relating to public health must be kept uninfluenced by any political considerations or policies. Just as your honorable bodies have shown great generosity and sympathy with the purpose of the Department of Education, I would urge that the Department of Health receive a liberal share of your attention. The state can make no more profitable expenditure than that wisely made in public health education and in advancing public administration. It is essential for future progress that the careers open to physicians in the public health service should be made attractive and that the compensation of health officials of all kinds should be more adequate to the service which they should be required to render to the public. In this way only can the best qualified men be attracted to the service and the best results for the state be attained.

"As a practical measure, the state should be redistricted in regard to health matters, so that each community could support a proper public health administration. There should be established throughout the state an adequate system of public health centers, in conjunction with local health activities, where the necessary public health supervision can be provided for all classes of the population,—for the expectant mother, the infant, the little child, the young adult, and the older men and women of our population.

"The state should subsidize the local health efforts and thus bring about a coordination of private and public health facilities so that every health center could command the services of a full-time health officer and the necessary public health nurses. Public health laboratories should be maintained in each of the larger cities where necessary work may be undertaken for the counties and the important diagnoses of infectious diseases made. Many diseases are insidious at the onset, and their subsequent course may be prevented if the condition can be discovered sufficiently early to administer relief successfully.

"I would urge most liberal provision for the Department of Health. Knowing the all too ready tendency to consider expenditure for health protection non-essential, the state must be prepared to step in and through protective and constructive measures, meet the situation and maintain our citizens at the highest pitch of their health efficiency."

THE RESPIRATION CALORIMETER AND ITS POSSIBILITIES

THE development of new things in medical progress hinges to a great extent upon the development of technical measures. The study of basal metabolism has advanced almost *pari passu* with the improvements in the ease of handling the respiration calorimeter. Remarkable work has been done, particularly in Boston and New York, in the last few years on the basal metabolism in various conditions; and the promise is for an even wider range of results from the application of Benedict's new and comparatively simple portable respiration apparatus.

Perhaps it would not be amiss to answer the question often put to the editor as to exactly what is meant by basal metabolism. The term is used to describe the actual fundamental metabolism of the body completely at rest and starving, which means the actual energy requirements for those vital processes which never cease. It has been found that normal basal metabolism varies with the square surface of the body, and DuBois has described a formula for easy calculation of body surface on the basis of height and weight. The estimation of oxygen consumption and carbon dioxid excretion furnish the basis for calculation, and with the calorimeter it is comparatively easy to measure both the oxygen consumed and the carbon dioxid excreted. Quite recently, J. H. Means and J. C. Aub[1] have published a splendidly complete article on the basal metabolism in exophthalmic goiter, which for the first time presents work on patients who have been followed before, during, and after various kinds of treatment. The paper is based on a study of 345 metabolism observations on 130 patients. A comparatively large series of normal controls was studied, including such things as diseases of the nervous system, pernicious anemia, Raynaud's disease, diabetes, and obesity; and, although there were slight variations from normal in the basal metabolism, the actual figures are quite different from those found in exophthalmic goiter.

Thirty-three cases are included in the group sent to the authors for differential diagnosis. The studies show that "most patients with goiter without clinical signs of thyrotoxicosis have a normal metabolism, and that such cases do not subsequently become toxic. The metabolism determination, therefore, seems to be an excellent means of differentiating toxic and non-toxic goiters. . . . In cases with suggestive symptoms, those patients with a normal metabolism do not subsequently develop exophthalmic goiter, while those with an elevation oftentimes do. In this class of cases, therefore, the metabolism determination appears to differentiate between true hyperthyroidism and simple neurasthenia, and makes possible a far earlier diagnosis of exophthalmic goiter than would the clinical picture alone."

Fifty-five cases of exophthalmic goiter were studied. These patients were studied both clinically and from the standpoint of the metabolism. Furthermore, they were studied before and after

[1] Means, J. H., and Aub, J. C.: Arch. Int. Med., 1919, xxiv, 645.

various kinds of treatment and for a period in some instances of several years. The basal metabolism on all exophthalmic goiter patients, as has previously been shown, is considerably elevated over the normal, an elevation which is likely to be anywhere from 25, 40 or even 90 per cent above normal. Since a quantitative determination of the excess basal metabolism is possible, and since this same quantitative determination can easily be made at various stages in the course of the disease, we have at our disposal a quantitative method of measuring therapeutic efforts. The authors applied this principle to the study of the effect of rest, quinin hydrobromid, Roentgen ray, and surgery; and, although at times it was difficult to differentiate the various factors that played a rôle in the ultimate result, the statistics offer almost mathematical proof and point to almost inevitable conclusions. Rest from one to three weeks, for instance, shows an average reduction of metabolism from +81 per cent to +67 per cent; this drop reaches a certain level and stays there, and in not a single patient was the metabolism brought within normal limits by rest alone. This statement must be modified by the fact that no experiments were performed on patients enjoying rest for months or years. Quinin hydrobromid apparently has no greater effect on metabolism than has rest alone.

The effect of the Roentgen ray is very striking. The average metabolism before treatment was +63 per cent; after one or two treatments there was a reduction to +52 per cent for the group; after six or seven treatments there is a greater drop and, finally, two or three years after the fifth treatment, the group average metabolism is only +13 per cent, and "all the patients are leading normal lives."

The effect of surgery was studied in a similar way. In the series operated on the average metabolism was +46 per cent. During the first fortnight after operation, metabolism fell to +21 per cent, with a secondary rise after the fourth month after operation, followed by a progressive fall until in the third year the average is +13 per cent, and "all patients are back leading normal lives." It will be seen by comparing the surgical and the Roentgen results that the ultimate results are the same, but that with the Roentgen ray group improvement is gradual and progressive. Also, it will be noted from the figures just quoted that the Roentgen ray group had a higher average toxicity than the surgical group, the comparison being 63 per cent, against 46 per cent. The authors believe, on the basis of these figures, that the Roentgen ray therapy of exophthalmic goiter is to be preferred to surgery, inasmuch as the therapeutic end results apparently are the same and all the dangers incident to surgical procedures are eliminated. Of the nine known deaths occurring in the original series, five were directly the result of surgery. One patient, after prolonged Roentgen ray treatment, finally died of exophthalmic goiter, one after having been apparently cured by operation, one after an apparent cure by the Roentgen ray, and one after failure to improve materially under Roentgen ray therapy. The average duration of improvement in the Roentgen ray group up to the spring of 1919 was about five and one-half years, while that of the surgical group was three and one-fourth years.

The clinician will immediately ask if any relationship exists between these studies of basal metabolism and the clinical findings. The authors forestall this question by charts which show that in about 60 per cent of the cases there is a close parallelism between pulse and metabolism, and in the remainder a certain degree of parallelism. There is, however, but little relationship between metabolism elevation and pulse elevation in the individual case. However, there is no definite relationship between body weight and metabolism curve, nor could any constant relationship of blood sugar curve to end result be demonstrated.

Answering the question as to the value of metabolism as a guide to treatment, the authors conclude very definitely that "not only should the Roentgen ray be tried first in the management of exophthalmic goiter, with the idea that it may be sufficient to cure the patient, but also because if not alone sufficient to cure, it may render subsesequent operation safer and more likely to be followed by good end results. Surgery, we believe, should be employed with conservatism, and usually only after the Roentgen ray and other medical measures have failed. We also believe that after operation, if the metabolism remains elevated, the Roentgen ray should again be employed." The authors also believe that Roentgen ray treatment of thymus is quite as important as that of the thyroid.

Is there any prognostic significance in these metabolism studies? A study of the relation of pulse curve to metabolism curve shows two distinct types: (1) those with an extreme tachycardia and a moderate metabolism elevation, and (2) those with an extreme metabolism elevation and a moderate tachycardia. The end results show that the patients of Type 1 would compare about equally well with surgery or Roentgen ray alone, or with surgery preceded by Roentgen ray treatment; while with Type 2 surgery alone gives poor results, the Roentgen ray alone may cure,

but the Roentgen ray followed by surgery may be necessary in the more resistant cases. Four of the five patients dying following operation belonged to Type 2.

We have practically given the authors' conclusions in the body of this review. It seemed to us in reading this very clear cut piece of clinical investigation that the authors have presented one of the most important studies on the differentiation and treatment of exophthalmic goiter that it has ever been our pleasure to read.

EDITOR.

RECENT INVESTIGATION IN FILTERABLE VIRUSES

THE first filterable virus ever investigated was that causing a parasitic disease of plants. Since this time it has been shown that a virus can be obtained from a number of diseases which can be filtered through a Berkfeld or Chamberland filter, and the filtrate, when inoculated into human beings or some species of animals, will reproduce the disease. Among these diseases are yellow fever, poliomyelitis, and rabies. Some years ago Noguchi developed a special bacteriological method whereby he was able to cultivate an extremely minute globoid body from filtrates of poliomyelitis material, and with subcultures many generations removed from the original, reproduced the disease in monkeys and also recovered the globoid bodies from them. It is the belief of Noguchi and Flexner that this globoid body is the cause of poliomyelitis. Noguchi has since successfully cultivated another filterable organism, also a globoid body, from rabies.

Although it has been known from the work of Reed and Carroll that yellow fever is caused by a filterable virus, it is only recently that Noguchi has demonstrated that this virus can be cultivated and has reproduced the disease by inoculation of the cultures in animals. This organism belongs to the genus *Leptospira* and is, therefore, not a globoid body.

Nicolle and Lebailly[1] were the first to publish experiments which seemed to show that there can be obtained from the nasal secretions of influenza cases a filterable virus which will cause symptoms, at any rate similar to influenza, when transmitted to normal individuals and to a few monkeys.

Since this time, two groups of investigators have published quite a bit of experimental evidence to demonstrate not only that a filterable virus is the etiology of influenza, but that this filterable virus can be cultivated by a modification of Noguchi's method for growing the globoids of poliomyelitis, and that globoids constitute this filterable virus of influenza. These two groups are Gibson, Bowman, and Connor[2]; and Bradford,[3 5 6 7] Bashford,[4 5 6 7] and Wilson.[5 6 7]

Their work was done independently of one another and was carried on at about the same time and published almost simultaneously. It is most unfortunate that Major Gibson lost his life from influenza contracted when he was overworking in his laboratory in this investigation.

The culture medium devised by Noguchi consists of a piece of sterile rabbit kidney placed in the bottom of a tall, narrow tube to which are added ascitic fluid and inoculated material. The contents are then over-laid with a layer of sterile paraffin oil or vaselin. The two groups above mentioned used modifications of this method. Their transmission experiments to animals and their cultures must be considered very seriously, and are certainly at least extremely suggestive. The difference between experimental influenza in animals and in human beings is so marked, one must necessarily feel that there is an element of doubt until this work is further confirmed and amplified.

Bradford, Bashford, and Wilson[5] then studied not only influenza, but quite a number of other diseases, and have published extensive articles on influenza and infectious polyneuritis, and have also published preliminary reports on a filter-passing virus recovered from infectious polyneuritis and *encephalitis lethargica*, trench fever, nephritis, and rabies. From each of these diseases they have secured evidence leading them to believe that they are caused by globoid bodies which are similar to one another, and which they were able to cultivate by a modification of Noguchi's method and with cultures reproduce the disease in animals. They believe that in these six diseases they have satisfied Koch's four postulates. There is a considerably larger group in which they consider that they have as yet only

7. Bradford, Sir John Rose, Major General, K.C.M.G., C.B., F.R.S., A.M.S.; Bashford, E. F., Captain, R.A.M.S.(T.); and Wilson, J. A., Captain, R.A.M.C.: The Filter-Passing Virus of Influenza, Quar. Jour. Med., 1919, xii, No. 47, p. 259.

got the bacteriological evidence, *i.e.*, a culture of virus. These are mumps, measles, rose measles, typhus, scarlet fever, hemorrhagic chicken-pox, and vaccinia. This large list includes most of the infectious diseases, the etiology of which is at present unknown or not completely proved. If these results are confirmed and turn out to be true, they will be a remarkable addition to medical knowledge.

Their presentation of their experiments and data is unusually clear, simple, and systematic; and their claims are stated in a self-contained manner, with entire freedom from extravagance. The articles of Wilson, especially, are models of scientific presentation. There is no flaw which can be discovered in the experiments they published. The only thing one can say is not a scientific criticism of their work, but simply that it is so tremendous it seems almost too good to be true.

Unfortunately, there has appeared a scientific criticism of the work of Bradford, Bashford, and Wilson by Arkwright.[8] As criticisms go, this is an extremely fair one, as the investigation was done with the aid and material furnished by Bradford and Wilson. Also, these two latter investigators append notes at the end of Arkwright's criticism.

It must be said that Arkwright's criticism, which is a very serious and fundamental one, does not necessarily vitiate the correctness of the contentions of Bradford, Bashford, and Wilson. It would seem that although Arkwright's investigation was a thorough one, the three workers criticized have a much larger material which must be considered than that investigated by Arkwright. Wilson admits that the cultures examined by Arkwright were contaminated and states at the conclusion of his note "that it has not been proved that a filter-passing organism has been grown in pure culture in any of the diseases for which the claim is made." One infers from this that Wilson believes that he has successful cultures but that he has not the organisms in pure culture. We expect that Wilson will report further on this subject.

It is of special interest, in light of the work reviewed above, that Loewe and Strauss[9] have recently reported in American publications the successful cultivation of a filter-passing, globoid organism, by the use of Noguchi's original technic, from the nasal pharynx and central nervous system of cases of *encephalitis lethargiea*. They have also reproduced this disease not only in monkeys but in rabbits by inoculation with cultures and with sub-cultures of the twelfth generation of this organism. They have recovered the same organism from the infected animals and again reproduced the disease with it. The illness of the animals is a remarkable counterpart of the disease in humans. The gross and microscopical lesions of the central nervous system are also identical with those found in cases of *encephalitis lethargiea*. It is believed that there can be no doubt but that this is the etiology of *encephalitis lethargiea*.

It was the good fortune of the reviewer to see the work, cultures, and preparations of Loewe and Strauss, and he is convinced of the correctness of their results.—W. T.

RECENT WORK BY W. W. HERRICK ON MENINGOCOCCUS INFECTIONS

HERRICK[1] has demonstrated and emphasized two new facts. The first is that meningococcus meningitis is undoubtedly caused, in a large percentage of cases, if not in all of them, by localization of meningococci in the meninges after having been present, for a short or long time, in the circulating blood. This was demonstrated in several ways. It was soon found, in the Medical Service at Camp Jackson that in the early stages of meningococcus meningitis a positive meningococcus blood culture was often obtained. The portal of entry was not found but is probably through the nasopharynx.

This led Herrick to perform blood cultures on many soldiers who reported sick, with more or less indefinite symptoms. It was, therefore, possible to make blood cultures on a large number of individuals in the early stages of numerous diseases, including meningococcus meningitis. It was found that a considerable number of soldiers, complaining simply of feeling sick, usually with fairly high temperature, sometimes with chills, but without any meningeal symptoms whatever, were found to have a meningococcus bacteriemia as shown by a positive meningococcus blood culture. In spite of serum treatment administered immediately, some of these individuals developed a meningococcus meningitis, confirmed by the presence of meningococci and leukocytes in their cerebro-spinal fluid. In some who did not recover, this was also confirmed at autopsy.

1. Herrick, W. W.: The Intravenous Serum Treatment of Epidemic Cerebrospinal Meningitis, Arch. Int. Med., 1918, xxi, 541.
Early Diagnosis and Intravenous Serum Treatment of Epidemic Cerebrospinal Meningitis, Jour. Am. Med. Assn., 1918, lxxi, 612.
Extrameningeal Meningococcus Infections, Arch. Int. Med., 1919, xxiii, 409.

Herrick also demonstrated that some of these cases with meningococcus bacteriemia, when given proper serum treatment, never developed meningitis or symptoms of meningitis, and never showed meningococci in the spinal fluid. Some of these cases died because of their meningococcus blood infection, and, at autopsy, showed absolutely no indication of meningitis.

The second and most important fact brought out by Herrick is that, because meningococci are present as a general infection in the circulating blood, intravenous treatment with anti-meningococcus serum is of even greater importance than intraspinal serum therapy. He emphasizes this point, but makes it clear that intraspinal serum treatment should also be administered in the usual way, *except* in cases with positive blood culture but no signs of meningitis, either clinically or in the cerebrospinal fluid. In this type of case, it is pointed out that lumbar punctures should not be repeated as the mere lumbar puncture with withdrawal of fluid may cause circulating meningococci to localize in the meninges and set up a meningitis.

The treatment evolved by Herrick is to inject large quantities of antimeningococcus serum intravenously at frequent intervals, and smaller quantities intraspinally at somewhat longer intervals. About 100 cc. are given intravenously every eight hours and 15 to 30 cc. intraspinally until the case shows marked clinical improvement or shows a negative blood culture and absence of meningococci in the spinal fluid. Herrick found that the average case requires from 400 to 600 cc. of serum by vein, and about 100 cc. intraspinally.

Herrick's statistics definitely show the value of this energetic form of treatment. It is believed that the importance of vigorous intravenous serum treatment cannot be over-emphasized. Undoubtedly one of the best, if not the best method of introducing protective antibodies into the cerebrospinal fluid, is by introducing the immune bodies into the general circulation, withdrawing large amounts of spinal fluid, and thereby allowing the antibodies to be secreted by the choroid plexus into the cerebrospinal fluid.

A number of very important accessory facts were learned in the course of Herrick's work. It was found that, unless antimeningococcus serum has an agglutination titer of from 1 to 200 or 1 to 400 by the United States Hygienic Laboratory method of performing this test, the serum is not efficient in therapy. Some commercial sera were found to conform to this criterion; others were not. Only those which conformed were used by Herrick. At present, probably to a large extent because of Herrick's work, it is believed that commercial sera are properly tested and can be relied upon. We now know, however, that there are a number of different types of meningococci, as demonstrated by workers at the Rockefeller Institute and also by workers elsewhere, especially Gordon and Tullock. It was found by Herrick that in some cases a serum, with a proper agglutination titer, was not efficient in treating a given case. He concluded that this was because the meningococcus causing the disease in the individual belonged to a type for which there were no antibodies in the serum used. He immediately changed to another potent serum, but preferably tested out the potency of his sera against the meningococcus from the resistant case and used the serum which best agglutinated the meningococci recovered from the patient.

It was also found that cases which developed a relapse and needed further intravenous treatment, were subject to serious anaphylactic reactions. This could be generally prevented by gradual de-sensitization, although sometimes it was necessary also to inject adrenalin hypodermically.

Herrick also found in his large series a few cases in which meningococci localized in the joints, pleura or accessory nasal sinuses without developing meningitis, but the most of them also showed a meningococcus bacteriemia.

There is only one point to which exception can be taken and that is merely one of terminology. The word "sepsis" is erroneously used, and bacteriemia should be substituted.

To sum up, one must realize the following:

That Herrick's work demonstrates the extreme importance of energetic intravenous serum therapy of meningococcus infections, whether already localized in the meninges or not. Herrick takes special care to state that the original intraspinal treatment as outlined by Flexner, Jobling, and their co-workers is just as important as pointed out by these investigators. He has added, however, that, while intraspinal treatment should be continued, massive intravenous treatment is of even greater importance.

This investigation is one of the best which has come from the military laboratories during the War, and the method evolved should be applied in civil practice in exactly the manner outlined by Herrick.

It is certain that new facts recently brought out, such as the separation of meningococci into several different types, adjusting the therapeutic serum to the type of meningococcus causing the infection, and Herrick's method of intravenous treatment, are of tremendous importance in the treatment of cases of meningococcus infection

and are an important step in our proper knowledge of treatment of this dreaded disease.

NEW TREATMENT OF SUPPURATIVE ARTHRITIS

FROM time to time, as our knowledge increases, we find that certain time honored conceptions of therapy must be relegated to the shelf of historic interest to make room for newer methods. The former method of treatment of acute suppurative arthritis has been recently replaced by one as diametrically opposed to it as any method could be. For years we have believed that the *sine qua non* of the treatment of acute purulent arthritis was immobilization; now we find that excellent results are obtained by active mobilization. For the last century splints were being devised to keep the joint from moving; now the literature is filled with lists of exercises. We still realize the necessity of good drainage but, instead of thinking that rest was essential for this, we believe that many of the good results obtained following mobilization can be attributed to the freer drainage obtained by this system.

The old treatment of septic arthritis is well standardized. The wound was drained and the joint immediately immobilized. Drainage was carried out by means of gauze, tissue, or the insertion of tubing, usually into the joint cavity, often through and through. The immobilization was maintained by splints, casts, or extension devices. To quote from some of the standard surgical texts:

Nicholas Senn in his "Practical Surgery" advises free incision, ample drainage (a picture showing through and through drainage is given), antiseptic irigation, moist compresses, and "immobilization of the limb in a useful position."

Rose and Carless in their "Manual of Surgery" say, "in the early stage (of acute arthritis) the limb must be elevated, absolutely immobilized, put into a position that, if ankylosis subsequently obtains, it may be of some use to the patient. As soon as the symptoms point to suppuration, the joint should be freely opened, while the fixation of the limb is maintained.

De Costa, in "Modern Surgery," gives for the treatment of acute suppurative arthritis the following: "The treatment in this form of arthritis consists in prompt incision, evacuation, antiseptic irrigation, drainage, an aseptic dressing, and immobilization. Cure is followed as a rule by ankylosis, but in cases treated early a movable joint may be observed."

The Willems treatment for acute suppurative arthritis is, in brief, as follows: Drain the joint, usually through two lateral incisions. As soon as the patient wakes, after the operation, start active motions. These active motions are continued at regular intervals, many times throughout convalescence. In a knee case, the patient is gotten out of bed as soon as possible and forced to walk. The enormous number of injuries to joints during the war gave Willems an opportunity not only to perfect his method of joint treatment, but also to present it to the profession and have it widely adopted.

As in every war injury, the cases were operated upon as soon as possible. By thorough débridement all infected material was removed. The joints were irrigated by a saline solution and rinsed with ether. Primary suture of the capsule, muscle, and fascia layers, and of the skin was performed whenever the operator felt that this could be safely done. The limb was not splinted. As soon as the patient awakened from the anesthetic he was made to move the joint. The active mobilization was kept up from that moment until the patient was discharged from the hospital.

By active motion Willems meant active motion in every sense of the word. In cases complicated with fractures, active motions were maintained if at all possible. Fractures of the condyles, of the metaphysis, injuries to the epiphysis, or to the capsule did not in themselves indicate any contra indication whatsoever. In the case of the knee joint every effort was made to have the patient walk on it at an early date, even the day after operation if possible. Of course, where the fracture or joint injury was of such a nature that displacement might be feared, care had to be taken; but, whether in bed or walking, the patient moved the joint himself by means of the muscles accustomed to move that joint.

Passive motion can not substitute for active. Passive motion will not prevent atrophy of the muscles, will not enable the patient to gain confidence in his ability to move the limb, and may actually injure the joint.

Willems emphasizes the fact that in order to obtain good results the active mobilization must be

La Mobilisation active immédiate Méthode général de Traitement des Lésions articulaire. Arch. méd. Belges Bruxelles 1918, lxxi, 225-246.

performed in a definite, systematic manner. All motion pertaining to the joint must be carried out; extension, flexion for the knee; extension, flexion, rotation, abduction, and adduction for the shoulder. Each motion should be carried out as nearly as possible to the normal limit and kept up to the point of fatigue. After a rest of a few hours the motions should again begin. His patients were awakened once or oftener during the night to perform the exercises.

Patients had to be coaxed, commanded, urged, and wheedled, depending upon their willingness to cooperate, their desire to speed convalescence, and their natural courage or timidity. Where possible, group exercises or drills were performed, under a person qualified to give orders.

A septic condition supervening in a joint did not prevent active motion. The joint was drained, either through the original incision or through new incisions. In the case of the knee, Willems preferred bilateral incisions which were long enough to insure good drainage. No tubes or drains were inserted. The incisions had to be kept open from time to time as they showed tendency to close.

The treatment of a case admitted as purulent arthritis was similar; bilateral incisions, lavage, and active mobilization were employed, the incisions being left open. Drainage was found to improve with motion. At each step, in a case of septic arthritis of the knee, jets of pus would squirt out of the wounds. The general condition of these patients was found to be better than those treated by the immobilization method. They felt better, looked better, and the temperature reached normal much sooner. Active motion was not painful. Pain was experienced when the joint was displaced or when drainage was inadequate. Pain on motion developing some days after closure of a joint indicated an effusion into the joint, synovial fluid, blood, or pus. After this was drained off,—in the case of pus through reopening the wound or incisions as above mentioned,—the pain disappeared. In a purulent arthritis, pain and a limitation of motion occasionally developed as the joint healed, that is, as the suppurative process subsided and the joint became dry.

Willems and those who have adopted his methods claim extremely gratifying results. The convalescence is greatly shortened and the prognosis for a movable limb is very good. These startling results can be obtained in civilian practice as well. Willems' first reports on the treatment by means of active mobilization were in a case of hemarthrosis and hydrarthrosis. It is to be noted, however, that active mobilization can not be carried in a desultory fashion, but that the patients must be under careful supervision.

NUTRITION OF THE FETUS

A MOST noteworthy contribution to the question of the nutrition of the fetus recently has been published by the department of obstetrics and gynecology of Yale Medical School.[1]

Slemons, in collaboration with Morse, Bogert, Curtis, Morriss, and Standler, most carefully investigated the transition of non-protein nitrogen, urea nitrogen, sugar, fats, and lipoids from mother to fetus by a comparative study of certain chemical constituents in maternal and fetal cord blood. The chief importance of these investigations undeniably lies in the fact that they speak rather in favor of the mechanistic than the vitalistic conception of placental function.

The vitalistic theory assumes that the wall of the chorionic villi, as the result of the activity of certain enzymes present in the placenta, takes an active part in the placental interchange between mother and fetus. The mechanistic theory, on the other hand, regards this wall as a passive, semi-permeable membrane through which the exchange between mother and fetus occurs automatically as determined by the laws of osmosis and diffusion.

There can be no doubt that since the first paper of Hofbauer, medical literature shows a prevalence of contributions in favor of the vitalistic theory. This latter theory undeniably is more in accord with present biologic views, which regard the fetus, beginning at the very moment of fertilization, as a new individual which, according to Murlin, rather independent from the mother, is "capable, even in the face of difficulties, of looking out for its own nourishment at every step of its development."

Of necessity, the fetus can procure the nutritive material indispensable for its normal development solely from the mother. Furthermore, practically all investigations into the relation of the fetal to the maternal metabolism concur in the one deduction, that the substances required by the fetus for growth *qualitatively* do not differ from those required by the adult body. From

[1] Slemons, J. Morris: The Nutrition of the Fetus, Yale University Press, 1919.

this point of view the one of the two main practical results of Slemons' researches seems the more acceptable: There is no diet specifically adapted for the state of pregnancy; the prospective mother may exercise perfect freedom as anyone else in the selection of food. Women may and usually do follow the dictates of appetite after they become pregnant as safely as they did before.

The other, in practical application still more important, question in the interrelation of the two metabolisms during pregnancy, pertains to the *quantity* of fetal food requirements. This latter question stands in close relation to the ever-interesting problem of influencing the growth of the fetus by specific diets during pregnancy. This problem recently was discussed most exhaustively by Ehrenfest.[2]

He believes that the possibility of such an influence in the effort to retard fetal growth has never been established either by clinical observations in man or by experiments on animals and, in his opinion, the assumption of such an influence is incompatible with present biologic knowledge. He summarizes physiologic and biologic teachings of the day as follows: "Modern physiologists and naturalists regard the germ cell as an individual organism and not as a maternal body cell. The process of fertilization activates and stimulates in this cell an anabolistic, proteosynthetic function. Probably by means of chorionic enzymes the embryo secures the building materials necessary for its immediate growth and full development. The embryo's power of assimilating its required nutriment from the maternal tissues is essential in its biologic aim and purpose of perpetuating the species. The germ cell is not a truly maternal cell and, therefore, unlike other body cells, is not at the mercy of maternal circulation and general metabolism."

As previously stated, the present, more prevalent belief in the vitalistic function of the placenta is not shared by Slemons as the result of his own investigations. Nevertheless, a simple consideration will show that not even so radical a change of views concerning placental activity would militate against the force of Ehrenfest's deductions.

It must be conceded that in the present state of knowledge we believe that hereditary factors, probably by way of endocrine gland activity both in mother and fetus, in the main determine fetal development. If, as is generally believed, all the required building materials are available in the maternal organism, then this growth-controlling factor, which undeniably exists, exerts its influence chiefly on the quantity of the substances assimilated from the mother; and this factor, if hereditary in character, must functionate almost if not entirely automatically. Modern biologists seem inclined to regard chorionic enzymes as the peripherally active agents of this central, development-controlling mechanism (endocrine system?). But even if, as Slemons seems to show, chorionic villi are not endowed with such functional ability, still the existence of such a controlling center could not be denied. Therefore, it is not surprising that in spite of this essential difference of views concerning placental function, almost identical with Ehrenfest's conclusions, Slemons states in regard to the second practical aspect of the problem of fetal nutrition: "There can be no justification for measures intended to restrict the growth of the fetus for, when rigidly carried out, they tend to weaken the mother."

Ehrenfest emphasized that such mistaken attempts of retarding or inhibiting the normal development of the fetus by diet restrictions have no direct relation to the fact that persistent overeating might possibly, not by means of necessity, lead to abnormal fat growth in the fetus. "Conclusive evidence has been adduced that certain substances, present in the maternal organism in abundance or to a pathological degree, as a rule, are carried to the fetus," but "the transmission to the fetus of substances essential for its normal development proceeds automatically." Practically the same thought is expressed by Slemons: "She may be careful to avoid over-growth of the fetus, but should not adopt a diet so limited as to interfere with normal development." H. E.

[2]Ehrenfest, H.: Can Labor be Facilitated by a Specific Diet of the Mother During Pregnancy? Am. Jour. Obst., 1919, lxxx, No. 4.

THE FEEDING OF HEALTHY CHILDREN

We are naturally more used to preparing food for invalids than for normal appetites, says Marion Price in a contribution to the December issue of the *American Journal of Nursing*. Training the healthy child in the proper food habits is especially important to the well being of the child. During the first five years of a child's life its natural antipathy to anything except the feeding bottle must be overcome, and such other articles must be gradually added as cereals, soft boiled eggs, crackers, zweibach, bread and butter, spinach and orange juice. A child properly accustomed to a regular, plain diet will not be retarded in growth nor go to the other extreme of craving rich and unwholesome foods.

Specific diets are not suggested, but the fact is emphasized that the majority of children's ailments are due to improper feeding and that often a youngster is blamed for irritability and bad temper when in reality he is suffering from nervous indigestion caused by unsuitable foods. To prevent sickness and insure perfect health among children we must emphasize the necessity of good, wholesome food given at regular intervals under cheerful conditions.

THE MEDICAL ASPECTS OF HEALTH INSURANCE ADMINISTRATION

By E. H. LEWINSKI-CORWIN, Ph.D., Executive Secretary, The Associated Out-Patient Clinics of the City of New York

THE subject of health insurance has passed the period of academic discussion; it has become one of practical politics, and before long the proposed measure will become law in our more progressive states. It, therefore, behooves all those concerned in the matter to transfer attention from the bootless discussion for or against social health insurance to the administrative details of the proposed new measures.

SOCIAL INSURANCE SEEMS TO BE ASSURED

Social insurance does not mean socialized medicine but means that medical care shall be universally available.

The question of medical benefits must be defined on a basis that will be possible to carry.

Matters of administration must leave the physician free to use his own best judgment and his obligations in the service should be only of a professional nature.

Even the goal of universal medical care should not permit a lowering of any single one of the high tenets of the medical profession.

Of all the problems of administration, those pertaining to the "medical benefit" are most baffling, not only because of the intimate human relationships involved, but also because with the introduction of universal health insurance the foundations of the present day practice of medicine will be rearranged.

Clear Understanding Forestalls Difficulties

If, in the callow beginnings of social insurance on the Continent and in England, the importance of a clear understanding of the intricacy of administrative details had been appreciated, unfortunate developments associated with health insurance could have been obviated. Fortified by the knowledge of the shortcomings of the older schemes, we are in a position to draft legislation which will eliminate from the start the unsatisfactory features of its European precursors and which will constitute a distinctive American contribution to administrative policy in social welfare.

Fortunately for the proposed measure, the leaders of the American medical profession have exhibited from the beginning an acute and wholesome concern in the subject of health insurance. Appreciating the social importance of the proposal, and realizing that a purely negative or indifferent attitude toward it might lead to ill advised legislative enactments if the whole burden for their formulation were left to laymen not cognizant of the basic conditions of medical practice, the medical men, individually and through their organized bodies, have taken an active, frequently hostile, but invariably helpful, interest in the proposals submitted; and as the successive bills for universal health insurance are being introduced in the legislatures from year to year, they exhibit a truer understanding of the administrative difficulties involved and bear the earmarks of the constructive thought and criticism of the medical profession.

After a trenchant analysis of the laws in foreign countries, the Committee on Social Insurance of the American Medical Association offered at the annual meeting of the Association in 1917 the following fundamental demands which the medical profession should insist upon in health insurance legislation:

(1) Freedom of choice of physician by the insured.

(2) Payment of the physician in proportion to the amount of work done.

(3) The separation of the functions of medical official supervision from the function of daily care of the sick.

(4) Adequate representation of the medical profession on the appropriate administrative bodies.

Free Play for Spirit of Emulation

A brief explanation may make clearer the reasons for these demands. Freedom of choice of physician by patient, subject to the physician's willingness to serve, is not only fair to the patient with whom the personality of his physician counts for a great deal, and to the physician whom it protects against certain types of patients for whom he does not care, but it leaves the practice of medicine undisturbed and provides room for the free play of the spirit of emulation.

In order that emulation should not degenerate into cutthroat competition, two additional proposals were subsequently made by medical critics. One was to the effect that no physician should be permitted to have under his care more than a stipulated maximum number of families, this to be determined in a pragmatic way on the basis of experience under urban and rural conditions. This theoretically sound provision would probably prove difficult to enforce, and for this reason it was omitted from the last draft of the 1919 New York bill. The second very practical suggestion was that a minimum scale of fees should be initiated by the doctors through their county societies. Their scale then goes to the chief of the health insurance bureau, who is himself a physician, for his approval.

The Dread of "Contract Practice"

Of all the possible results of health insurance none is more feared by the medical profession than the ineffective and deadening "contract practice." They are apprehensive lest the efforts of the last two generations to raise the standards and morale of medical practice in America be obliterated by the injudicious introduction of a wholesale, cheap capitation basis of payment. It is stated that wherever it has been tried it has resulted in overwhelming the practitioners with unnecessary and trivial work, in depriving them of the stimulus and opportunity for scientific treatment, in divesting them of the dignity of their calling, and in jeopardizing the whole future of medical progress. The demand of the Social Insurance Committee of the American Medical Association, quoted above that payment be made in accordance with services rendered is but one of the safeguards which the medical men feel must be thrown around the system. Under the New York bill the physicians initiate the method of payment as well as the minimum fee schedule. By thus removing the fear of capitation payment and lodge practice, the profession is safeguarded in this important respect.

Duties of Physician Purely Professional

In order to obviate another of the inadequacies of the European systems, notably that of affording opportunities for malingering and valetudinarianism, the demand has been made that the responsibility for certifying to the illness of the insured be removed from the physician giving treatment, and placed upon a medical officer especially engaged for the purpose. In this wise the patronizing of "easy" physicians, observed in Germany and elsewhere, is done away with and the physicians are freed from all responsibilities except purely professional duties toward their patients. Here again the present day relations between physicians and patients remain undisturbed.

The administration of health insurance, dealing as it does to a large extent with questions of medical care and relief in its multitudinous forms and under a great variety of conditions, obviously calls for expert guidance and advice. With the shifting whims of democracies and their demagogues, often impatient of or openly inimical to experts, it is imperative that the vital interests of a great scientific profession, whose very existence under a universal health insurance law depends upon its intelligent administration, be amply and adequately protected by proper representation on all pivotal administrative boards and thus be safeguarded by precise legislative enactments.

Recognition of Medical Demands

All of these basic medical demands have been recognized and incorporated in one form or another in the bills introduced in the several states. Several additional safeguards were considered and added to the last draft of the New York bill. One was the substitution of a single state-wide panel for the many local panels of physicians. It was pointed out that a multiplicity of local panels creates boundaries for and artificial limits to medical practice, that patients in certain localities might be seriously inconvenienced by such limits, particularly with reference to the selection of specialists. Accordingly, a state-wide panel was recommended for incorporation in the law.

From this brief account it may be gathered to what extent the medical arrangement of American legislative proposals on health insurance have been moulded by the criticisms of the medical profession and, as a result of it, we shall eventually have laws which will indubitably prove to be infinitely superior to their European forerunners.

There are, however, at least two considerations which make the medical profession chary about health insurance, both of which can only to certain extent be safeguarded by statute.

Intelligent public opinion and a proper enlightenment of those who will benefit under the law as to the paramount importance of a high grade, conscientious, and scientifically conducted medical practice constitute the only safe reliance that the standards of medicine will not suffer should the cost of the medical service under the insurance law prove to be higher than the beneficiaries may anticipate. The medical profession consider it of prime importance that, before health insurance is adopted, those who will pay for it should clearly

understand the costs involved in securing adequate medical service on a wide social scale. The whole purpose of the law would be defeated if the medical service under it should suffer because of a parsimonious policy on the part of the insurance funds. And yet the cost, large as it be in the aggregate, does not seem to constitute an unbearably heavy burden when properly distributed. According to a recent computation made by a distinguished authority on matters of public health administration and hospital management, based, it is true, on rather too low units of cost, the expense of health insurance to the workman, including cash benefit, hospital care, maternity benefit for his wife, burial benefits, and other medical care for the family, amounts to $28 per annum. Other authoritative estimates place the cost considerably higher. The last draft of the New York bill excludes the dependent members of the family of the insured person from the benefits of medical care and this, of course, reduces the cost very materially. Whatever the cost may be, it should be clearly recognized beforehand, to obviate any "jump in the dark."

Medical Standards Must Not Suffer

There is a second consideration which must not be lost sight of: The relation of health insurance to "group medicine." Medicine has made great strides during the past generation. Specialism has come to stay and "group medicine" is the form of practice which insures scientific satisfaction to the physician and the greatest amount of effective service to the patient. No one physician can master all the details of the science and art of medicine and the intricate diagnostic and therapeutic technic connected with the treatment of disease. The practice in our best hospitals is based on this recognition of the advantages of group medicine. The services of various specialists are constantly asked for and freely given in a hospital medical team. The same begins to be applied in out-patient work. It is the modern trend; and legislation of no kind should interfere with it lest medical progress and medical teaching be jeopardized.

Under a health insurance law the tendency will inevitably develop for patients to resort to individual physicians rather than to medical institutions. This will be prejudicial to group medicine. In order to forestall this tendency as far as feasible the last bill introduced in the New York legislature contained a provision for the payment of physicians for services rendered to insured persons in hospitals or dispensaries. However, in spite of such a provision, and notwithstanding the educational work that may be attempted, at first there will be a shifting from the hospitals, and particularly from the dispensaries, to the private offices of physicians. This tendency will probably be stronger among the general medical patients than among those seeking the advice of surgeons or other specialists. The tendency may be somewhat offset by the increased use, as a result of health insurance, of institutional treatment by those who today cannot afford specialists' fees but who will not accept medical charity. It is probable, however, if proper guidance is provided, that the public will come to realize the advantages of group medicine, and our splendid medical institutions and schools will not suffer because of health insurance.

LOW AUTUMNAL MORTALITY

The general average of public health is better than it has been for a long time according to the reports of the Metropolitan Life Insurance Co., Industrial Department. If serious influenza sequelae are to affect health averages, they are yet to be noted.

In their published comparison of death rates per 100,000 from July to November the causes of death named in order of importance are: (1) tuberculosis, all forms; (2) organic disease of heart; (3) accidents and unspecified violence; (4) Bright's disease; and (5) pneumonia, all forms.

CAN'T CUT MEDICAL COURSES

Medical students who interrupted their studies to answer their country's call to arms cannot count war service as part of their qualifications for diplomas, according to a decision rendered by Supreme Court Justice Delehanty. The decision was given in the case of an application by students of the New York Homeopathic Hospital and the Flower Hospital for mandamus directing that they be admitted to practice at once. They alleged that a former dean of the school had promised them their diplomas at the end of the year of 1918-1919 in return for war service, although the full course required another year of experience as hospital interns.

BEDSIDE TRAINING FOR PHYSICIANS

A means of providing whole-time physicians for hospitals which at the same time would afford clinical educational facilities for physicians is embodied in a recommendation by Mr. E. W. Morris, House Governor of the London Hospital, which is reported in the *Prince Alfred Hospital Gazette*. Whole-time hospital service is the only way the doctor can learn his profession. A staff of medical men should be provided who would give all their time at fixed salaries for five years, during which period their hospital time and salary would gradually be reduced so as to enable them to slide into general practice without loss, the hospital connection making it possible for them to become consultants. Such men should have under them not more than twenty or thirty beds, so that they might have a chance to study their patients, and should also have paid assistants in carrying out research. The patients would have the advantage of better attention and improved service; the men would reap the great educational advantage of being on a hospital staff.

THE STATUS OF INFLUENZA

By D. M. Lewis, M.D., New Haven, Conn.

BY REASON of three factors operative in the past two years, it is possible to show at this time what the status of influenza is, and, consequently, show the measures that may control epidemics. The factors are (1) that an unusual number of young adults drawn from wide areas of this country not only have been placed by thousands into camps but have also been transferred in numbers from either one camp to another or to another country; (2) that among such pharyngitis, tonsillitis and bronchitis were included as communicable diseases; and (3) that as never previously possible, there are country-wide records of bacteriology, not only of the diseases just mentioned but of large numbers of so-called healthy contacts. This material, when studied epidemiologically in connection with the vital statistics of the country at large or by states, is so voluminous in detail that a summary only is given.

Some Suggestive Parallels

Three periods are of importance; the first is that of the first six months of the life of the camps, October, 1917, through March, 1918,—a period of measles and pneumonia. The second is the six months ending December, 1918, a period of influenza and pneumonia. The last is the post-influenza period, the first six months of 1919. A study of the 1917 report of the Surgeon General shows definitely the well known fact that the rural population has a high frequency or epidemic measles only after urban contact. Irrespective of whether the camps were National Guard or National Army,—so divided at first on the supposition that the National Guard had received previous training in sanitation, the distinction became lost with the November, 1918, drafts—the highly urban units had but few measles as contrasted with those from rural districts.

A point not appreciated unless the record of these camps is charted is that there is a similar proportionate primary and secondary pneumonia, and the time frequency or epidemicity of the pneumonias is similar to that of measles; further, the bacteriology of the secondary lobar pneumonia follows the type of that which is primary; *i. e.*, in one place type I or II in another type III or IV, whereas the primary and secondary bronchopneumonia was either the streptococcus or type IV pneumococcus. Thus during the first three months of measles and pneumonias the sum total of pneumonia deaths for three of the rural National Guard camps was more than 500, as contrasted with a total of 4 for the three National Guard camps predominantly urban. The same is true of a contrast of National Army camps. To be emphasized is the general accord of lobar pneumonia having a fatality of from 10 to 15 per cent where that for bronchopneumonia, whether primary or secondary, is from 40 to 60 per cent. There is evident, then, an unappreciated civic finding that primary bronchopneumonia is a problem of greater import among young adults than lobar pneumonia, whether or not in association with measles.

If now the statistics of pharyngitis, tonsillitis, and bronchitis are taken, there is found a proportionate frequency in advance of the measles and the pneumonia; and further, the bacteriology of both sets are alike. There are also statistics that the so-called healthy carriers, when examined at or after the height of the frequency of the measles pneumonias, are in accord with the varying bacteriology of the different camps. Alone of all the camps, the statistics of Funston have a difference which proves certain points. One of the most prevailingly rural camps, "there was a something about conditions or perhaps the type of measles prevailing which prevented the usual heavy onset of pneumonia following measles." Statistics show that alone of all the camps, all measles cases were given on the first, fourth, and eighth day streptococcus vaccines; that alone of all rural camps that there was no proportionate amount of primary bronchopneumonia, and, further, that during the measles frequence a dichloramin-T spray was used generally throughout the camp.

What Happens After Transfers

If we examine what happens after transfers from camp to camp, it is found, for example, that Custer, which was a two-thirds urban camp, had no deaths from either primary or secondary bronchopneumonia during the first three months, for the reason that they had but two such cases in all, following a moderate amount of measles. During January, 1918, there were transferred to that camp from Jefferson Barracks some 1,500 soldiers, one-fifth of whom were ill with respiratory diseases, including measles and pneumonia. Two days after arrival 600 more reported at sick call. Two weeks later from the same place there

arrived 99 men, of whom 25 had tonsilitis, 10 suffering from bronchitis, and 3 from measles. After this time both primary and secondary bronchopneumonia became frequent. In March more than 1,000 men came in from Dodge with a respiratory sick rate of 62, as compared to the then existing camp rate of 15. From these two sets of transfers there arose a streptococcus frequence. In May, for the first time, there was found present type I pneumococcus among negroes with pneumonia; these were among a draft of Alabama negroes arriving the end of April. The same was true of other urban camps, like Upton, Grant, Devens, and the predominant organism introduced leading to the primary or secondary pneumonias may again be found in the third period. At the end, then, of the first six months the mortality rates for disease only, represent mainly that of measles pneumonia. It is also noteworthy that an exactly analogous situation arises with reference to German measles and pneumonias.

Secondary in importance is the frequence of meningococcus meningitis. During and following measles frequency or epidemicity there is proportionate incidence of meningitis, even when is excluded the fact that a large part of the high frequency of Pike and Dodge was laid to transfers from Funston. Other than a remarkable fact that in one of these camps 80 per cent of the measles patients in one ward were meningococcus carriers, statistics show that the chronic carrier is a contact of the case, that both are of the same type as contrasted with frequent fresh carriers, and, what is to be emphasized, the carrier and not the case is contagious. As contrasted with so-called healthy carriers of the streptococci or the pneumococci by the bacterial presence of the organism in nasopharyngeal cultures, the percentage of carriers of meningococci is much smaller; yet the percentages found in camps bear a rather definite proportion to the case frequence and the proportion is greater when the so-called chronic per cent is considered. The latter are those in whom the meningococci are present in great numbers, even to pure cultures. This point should be remembered for its future reference.

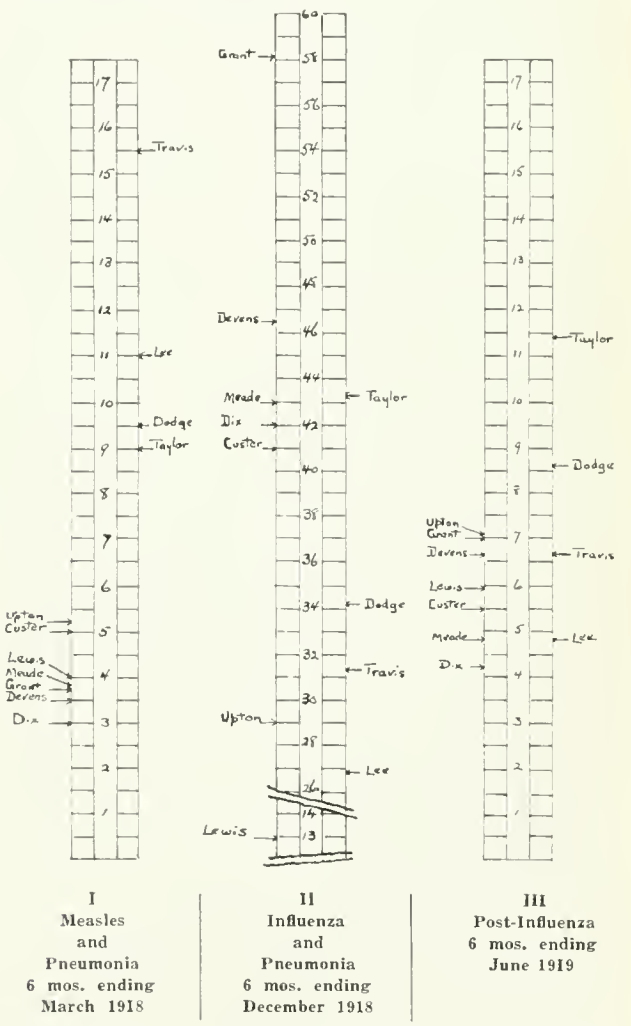
Of moment is also the fact that in those camps only where there was high frequence of streptococcal types manifested by otitis media and septic throats was there an ensuing frequency of cases of scarlet fever. In one camp where such conditions were excessive there was a following epidemic of scarlet fever.

During February and March, the last two months of the first period, there were, as we have seen in the case of Custer, infections transferred from one camp to another in bulk, so to speak; Dodge with its streptococcus "flu" introducing it into Custer; Grant with a secondary grade of measles more severe than the previous genuine type, with prevailing streptococcus bronchitis and tonsillitis gained from Funston. Noteworthy at this time were the conditions at Fort Sam Houston, where in post-mortems streptococci predominated, there were a few cases where the B. influenzæ was present in the blood and the tissues; it was present in 5 of 13 sputa examined, and in these 5 at post-mortem the organism was present in the lungs. It is also recorded that, contrary to civic life, a streptococcus actively hemolytic was present in the camp if the individual examined was subject to epidemic coryza, tonsillitis, laryngitis, or bronchitis.

Near the close of this period and continuing from March 1 to May 26, 1918, there was an epi-

Mortality Rates: (Annual) Disease Only in Certain Camps for Certain Periods

Camps on Left = + 50% *urban.*
Camps on Right = — 50% *urban.*



A study of disease incidence in certain camps over six-month periods and a comparison of the successive types of infection, correlated with additions and transfers from camp to camp, form a new basis for conclusions to be drawn from the recent epidemic of influenza.

demic which, as reported by Opie *et al.*,[1] consisted of five waves of influenza. The essential points are that in the first two weeks it swept the entire camp; that the four succeeding waves were limited to transfers from other camps in the interim; that successive outbreaks of pneumonia followed this influenza and each was limited to the organizations as they were attacked by the influenza; that while measles pneumonias previously in this camp had been 79 per cent bronchial, in this epidemic between 93 and 98 per cent were lobar and preëminently pneumococcal types I and II. Examination of the healthy men showed 61 per cent carriers of types III and IV and 35 per cent carrying B. influenzæ. Further, the pneumonia was characterized by the low mortality of lobar as contrasted with the preceding streptococcal bronchopneumonia of measles.

Unfortunately, no data are given as to any transfer of troops to this camp previous to February 28, when there is charted an initial frequency of influenza. It is stated and charted that influenza had been present from the beginning of the camp; if a closed camp, that is, not having had transfers since its drafts in November brought it to its full strength, if before, during, and after measles and measles-pneumonia there was no frequence of primary bronchopneumonia, this fact, with the frequence charted of influenza of bronchitis and primary pneumonia smoldering during five months would have great bearing on the subsequent developments in this paper. In that Fort Sam Houston was the only camp whose record showed the B. influenzæ present before this epidemic at Funston, it is possible that transfers were made from that camp to Funston; or that the latter supplied material toward the end of January or early February to Fort Sam Houston. The important fact is that at Funston all the essentials of influenza, with the same high proportion of healthy carriers found after the epidemic, are present in no wise different from the "flu" of Dodge, save that the latter was streptococcal and, unlike the latter, was of low mortality.

Tracing the respiratory rates and illnesses in the American Expeditionary Forces, we find a respiratory rate maximum in January, 1918, 86 per 1,000 strength, decreasing progressively to 6 in May and increasing in June to 17. The statistics now show that, where studied, there was from April through July an epidemic of influenza due predominantly to the B. influenzæ. Not only was this present at the base ports but in the naval forces as well as among the Hindus. Following this mild epidemic there was an outbreak of meningococcus meningitis. The same was true among the British forces.

If now the statistics of civil life are examined for deaths from respiratory diseases, namely influenza and pneumonia, in the absence of case reports and bacteriology for the winter season of 1918, there is a notably decreased number of deaths as compared to the previous similar months of 1917 up to the middle of March. As I have previously shown,[2] there was an excessive death rate for the cities of this state and for New York City for the months of March and April over the previous months of the year and over the previous year. It now appears from the *Public Health Reports* that the same holds true generally for all states in the country. Further, the *Reports* show that for ninety-five great towns in England there is a first high peak death rate in latter June and July, while in India there is one for Bombay, Calcutta, and Madras from July 6 to 20. There are now also in the literature statements that during March and April such conditions were present in Baltimore and Detroit, for example.

Returning to the army camps and the second period, that of the "flu" and pneumonia, we are told that the epidemic appeared as out of a clear sky. At Devens, for example, on September 12 it was officially recognized; at Upton it is said to have begun abruptly on September 13, with thirty-eight cases from Devens bound overseas. After this it is stated to have spread South and West. The examination of the sick rate among the organizations at Devens prior to September 12, and the difference between the bacteriology of Devens and Upton as being typical of that obtainable for all camps thus far recorded, may be dwelt on at this time. On the first of September the two companies of the division subject to the earliest and hardest attack showed an excessive sick rate; on September 7 there was an admission from one of these companies for meningitis and the day following a dozen more from the same company; on the fourth, hospital admissions were twice those on the first; on the eleventh twice those of the fourth, and not until complicating pneumonias were increased was the situation diagnosed.

When, then, the epidemic gained headway there had been present an extensive mild epidemic disease which was regarded as no different from that existing during the spring. Blood cultures gave positive results in approximately one-fourth of more than one hundred cases; two-thirds were type I and II pneumococci, one-third type IV.

[1] Opie, Eugene, et al.: Pneumonia at Camp Funston, Jour. Am. Med. Assn., 1919, lxxii, 108.

[2] Lewis, D. M.: Epidemiology of Influenza, Bost. Med & Surg. Jour., November, 1919.

One case, only, gave the streptococcus hemolyticus. This confirms their statement that two-thirds of the cases were lobar and one-third bronchopneumonia. In 62 per cent of pneumonia sputa, pleural fluids, and fluids from the nasopharynx, the lungs at post-mortem, occasionally from the heart blood and accessory sinuses, and frequently in pure cultures, there was found the B. influenzæ. At Upton the streptococcus hemolyticus was said to predominate and, clinically, in the majority of instances there was a tonsillitis which, with its thin, delicate membrane, was differentiated from diphtheria and Vincent's only by bacterial exclusion. A record of sputa findings shows 60 per cent pneumococcus type IV, 20 per cent streptococci and 5 per cent pneumococci types I and II. While at the beginning there was but 2 per cent B. influenzæ, later improved technic enabled its recovery in 38 per cent of cases, notably in conjunction with type IV. The existing flora of the predominant pneumonia at Devens was type I and II pneumococcus; this was the content of the Depot Brigade, and notably a previous draft of Alabama negroes among whom there was during August a high rate of illness, especially pneumonia, "permissible as being in negroes." The streptococcal content at Upton had been present during the spring.

Explains the Clinical Transition

If now we go to the central mid-western camps, Sherman, Grant, and Custer all show by post-mortems varyingly slight excesses of pneumococci IV or streptococci, the latter mostly hemolytic for Grant and Custer; non-hemolytic for Grant, while at Grant reports indicate that of the excess of pneumococcus, type II predominates over type IV. Nasopharyngeal surveys at or just before, as at Custer, confirm the findings. Exceptionally were influenza bacilli found. There is, as at Devens, the same evidence of a continually increasing respiratory rate with pneumonias during all September. With a certain something happening, an epidemic is officially on, as is well illustrated at Sherman. After an atypical picture of catarrhal infection of the respiratory tract with fever, cough, and conjunctivitis, and little or no leukocytosis, gradually in five days the type changed; the transition was rapid;— a condition suggestive of chlorin gas poisoning present, manifested as an acute inflammatory pulmonary edema which diminished as the bronchopneumonia increased.

In this connection, the throat and nasopharyngeal cultures showing 54 per cent pneumococci and but 4 per cent hemolytic streptococci, the sputa of pneumonias showing 80 per cent type IV pneumococci, and all the positive blood examinations showing type IV contrasted at postmortem with 53 per cent pneumococci and 47 per cent hemolytic streptococci may well explain the clinical transition. Its importance, I believe, is great, in that such a clinical transition led to the decision that influenza was epidemic at Custer. With the fact that these camps had during March their streptococcal content transferred to them from Dodge and Jefferson Barracks, with the fact that this epidemic hit disproportionately the new divisions which had been in camp but a month or more, as contrasted with the Depot Brigade, which was left over from the spring, the residual endemic content of the predominant organism in less than one-third of a camp's strength finds highly inflammable material in a newly drafted division of upwards of three times the strength.

Although it would seem possible from the statistics of the American Expeditionary Forces that from their earlier epidemic proportions in August they transferred influenza to this country, the difference in bacteriology of the Chelsea Naval Station, with its high streptococcal hemolytic content as compared to Devens, makes such a transfer improbable, the more so as the situation at Puget Sound and the Philadelphia station were both like that of Chelsea. It is further strengthened by the fact that where the Chelsea Station had during September and October hemolytic streptococci in 13 per cent of cases, during December and January, 1919, with the exception of one type IV and one non-hemolytic streptococcus in December, all pneumonias were streptococcus hemolyticus. That the epidemic in the American Expeditionary Forces was less severe, although going on at the same time as in this country, should be logical, in that the expeditionary forces had gone through streptococcal and type IV pneumococcal experiences before leaving this country, certainly in many of the camps. The increase strength from less than 300,000 at the end of March to one and one-quarter million in August should be remembered. That this country was also transferring during August and September influenza abroad is a matter of statistics, although the absence of bacteriology makes proof unavailable at present.

Equally large statistics in different municipalities as to the specific variations in bacteriological content by regions and with reference to the spring are not available. Only where the incidence in a new division entering a camp during the summer is not the prevailing high rate, but is low similar to that of the residual endemic camp infection, could be argued the penumonic infection of the community or region from which

that division came. Most suggestive, as shown by the mortality rates illustrated, is a notable reverse ratio of the camps: those high in the first period are low in the second. With full statistics of all the camps, the lower death rate curve for certain western and southwestern cities and states may be so explained, as also their higher rate for deaths during the spring.

There are few available detailed statistics of the camps for the post-influenzal period. Much may be gained from the weekly report of diseases. Analogous to the Chelsea Naval Station with its second wave, one of pure streptococcus infection, the higher influenza and pneumonia, including deaths of Devens, Upton and Lewis, for example, over Custer, can be reasonably assumed by the higher streptococcal content in the first three over Custer. In fact, it is striking how the average mortality for the three periods balances; two years obliterated the difference in mortality between predominant urbanity and rurality, a difference originally marked, but changed despite the fact that drafts for the new divisions came from the same communities for the same camps during the later periods as well.

The Facts as Demonstrated

Until the detailed statistics of camps, in terms of divisions, their transfers and periods of residence, residuals, (depot brigades, for example), and large bodies of casuals, can be exactly traced by specific infections and specific bacteriology the following demonstrated facts are worthy of attention:

(1) All respiratory diseases are bred during or after an appreciable amount of inflammatory disturbances of the upper respiratory tract.

(2) Isolation of all such cases of inflammation do not control those of the ensuing respiratory diseases.

(3) A high content of healthy carriers of a specific organism may be found during or after such a frequency of inflammations due to that organism, and may at the time be shown to be specific, as are the inflammations for one locality; they may be divided into two classes, the one where even pure cultures may be obtained from the mucous surfaces, the second in infrequent numbers or only in pure cultures in the underlying tissues. The first class are among the close contacts of the case; they are, as in meningitis and diphtheria, called chronics, and are in sufficient numbers to explain the existing cases.

(4) There is a large group of these organisms which produce bronchopneumonia: the bacillus influenzæ, the streptococcus viridans and hemolytics and the set composed of type IV pneumococcus, streptococcus mucosus and diplostreptococci; in the absence of cultures until late in the disease, the meningococcus has not infrequently been a missed type. Their absence has determined the absence of such complication in the exanthemata; their presence in the absence of the exanthemata may produce a very similar picture clinically; during certain seasons and of certain frequence, such cases are called grippe; when epidemic, they have been called influenza. These organisms have been endemic for so long that epidemics with pure cultures of one organism only should not be expected. Pandemic, earlier waves of low mortality manifest as epidemics of endemic community bacterial content determine following waves of consequent increased virulence. Variations in succeeding waves have been possible from the introduction of a different organism present elsewhere in a former wave.

(5) There is direct evidence that during latter 1917 the influenza bacillus was present in small frequency in the American Expeditionary Forces at Fort Sam Houston and Funston. That transfers from Funston abroad after the epidemic at Funston caused the epidemic in the American Expeditionary Forces rather than previous small frequency, or than the present assumed focus endemic in France in the spring of 1918, lack as yet the time of transfers from Funston but agree with the different bacteriology of the spring influenza of France. Also, later proof may show that Funston seeded other camps in this country. Contra, as in Custer, where there were no transfers from Funston after the spring epidemic, there was no content of influenza bacilli in either cases or carriers.

(6) Public health officials, state and otherwise, do not make practical use of vital statistics: a country-wide, definitely marked, increased mortality for pneumonia and influenza during March and April should have called out the unusual activities employed too late in the second wave. Of moment, in its relation to influenza, the proportionate increased deaths during those two months for all forms of tuberculosis, also country-wide, was not made use of.

(7) There should be noted at this time that the reported frequency of the presence of the influenza bacillus in cases of measles, diphtheria, scarlet fever, whooping-cough and tuberculosis, for example, which is being used as an argument against the specificity of the organism as a cause of influenza, may, in the instances where the time period is given, be shown existent in that community subsequent to an influenza or grippe epidemic. Such facts are presumptive evidence to the epidemiologist why the individuals were susceptible

to those diseases as well as why the diseases named have their waves of frequence.[3]

The measures for control of influenza then mean, (1), either the coining of new specific terminology for the very similar respiratory diseases caused by other pathogenic organisms than B. influenzæ; or, better, the diagnosis of the different component parts of the respiratory tract in terms of their bacterial content: thus, pharyngitis-influenzal, pneumococcic, streptococcic, meningococcic, etc., having regard for the fact that as a recent case of a different disease, individuals may have in the upper respiratory tract more than one apparent pathogenic organism, and that as a recent contact of an active carrier of a yet different pathogen, he may further have acquired that organism, also. (2) As may always be shown, no frequency of respiratory disease can arise without vital statistics giving at least a warning in the absence of possible bacteriology in ample time to control the situation. (3) Of the greatest importance is the isolation of carriers active in the sense that they are throwing off from inflamed mucous surfaces specific organisms in amounts sufficient to explain contact infection. Other than definite results obtained in a few camps by antiseptic sprays used on all healthy contacts, absence of control of the respiratory diseases, (which control was expected by hospitalization of all cases of the earliest manifestations), would seem to lie definitely in the absence of control of carriers.

SO-CALLED SHELL SHOCK IN THE GREAT WAR

By TOM A. WILLIAMS, M.D., Corresponding Member of Neurological Society of Paris, Etc., Washington, D. C.*

DURING the war the British Minister of Labor was reported by the newspapers to have stated that under no conditions should a sufferer from shell-shock ever be sent back to the trenches. Even if Mr. Hodge was speaking only of cerebral concussion, his statement is untenable, for in the French army innumerable soldiers have returned to the trenches and have done good service in spite of concussions so severe as to keep them in hospital for months.

But if the minister included under "shell-shock" those disturbances of the emotions which occur in some individuals who have been subjected to bombardment, then one can scarcely imagine a statement more deleterious to the morale of the army, for the statement implies that the disturbance of the system caused by explosions is incurable and hence as much to be dreaded as an incapacitating mutilation. Such a belief in the minds of the soldiery would furnish an intensely powerful suggestion towards anticipatory dread of the effect of an explosion. The contagion of this mental state continues to increase until cowardice replaces bravery in the character of the soldier, a condition which would have seriously endangered the winning of the war. This was a most pernicious pronouncement. It is fortunate that no American statesman allowed himself thus to step into a province purely medical. As a matter of fact, the term "shell-shock" was removed from the British official nomenclature, and the cases formerly thus comprised were sent back to advance hospitals under the rubric NNYD. They were there dealt with in accordance with the diagnosis reached. In the British service, very few NNYD's had received concussion. The concussions were nearly all diagnosed at the extreme front and were sent to the base when they were moved at all.

In both the French and British services, the procedure changed frequently during the war. The latest most usual practice in the French service was to send all nervous cases not dealt with by the regimental doctors or not requiring early surgical operation immediately to the neuropsychiatric center of the army zone. Among these cases were those known as *commotionés*, a classification which included many cases presenting sequelae of concussion, such as partial and fugitive modifications of reflexes and motility, restlessness or agitation with or without delirium, and modifications of the cerebrospinal fluid, which may show blood and generally presents hyperalbuminosis, sometimes a leukocytosis, and nearly always increased pressure as measured by the manometer. Of course, agitated delirium alone would very far from justify a diagnosis of concussion, but it is a frequent sequel of the primary comatose state.

Formerly included in the general term *commotioné*, later on many were differentiated as *emotionés anxieuses, confusionals* or *pithiatic* cases, in accordance with the very essential differences indicated by those terms.

It is gratifying that in the American service, this practice was followed from the first; for

*Being a report to the Surgeon General made in 1917 while the writer was adviser in neurology to the American Red Cross in France.

classification is not a mere academic subtlety, but corresponds to quite fundamental physiopathologic differences.

For instance, entirely apart from the effects of concussion, which are readily differentiable, a *confusional* case is a toxic one.[1] The patient is in need of treatment directed to his metabolism; and psychotherapy is not indicated.

An *emotive* case[2] is one in which instinctive tendencies, generally animated by fear dominate the patient's behavior; on the one hand, some occur because of the lowering of emotional thresholds from physiopathologic causes, which require further study, including that of endocrine apparatus; on the other hand, there occur those caused by besetment by dread emanating from an unpragmatic psycho-social attitude regarding the dangers to be faced in war.

The *anxious* case perhaps pathogenetically belongs to the same category as the emotive, and further study is required to see whether there is practical utility in separating this syndrome as certain French writers have done as regards the practice of military psychiatry. I believe that no essential difference exists between the two.

The *pithiatic*,[3] that is, moved by persuasion, is so called by Babinski as a substitute for the term hysteria, (caused by and removable through suggestion). Whether there has been injury or not, the *pithiatic* case is disabled only because he cannot bring himself to believe in the capacity that his physical status permits him. Whether he is misguided about himself and wants to return to duty, or whether he is only too glad to believe himself incapacitated in order to escape duty makes little difference as regards the treatment he should have. Nothing is more natural when an unwise solicitude is employed than the exaggeration of the temporary shock and confusion engendered by a violent explosion to a degree where the patient believes himself to be seriously damaged. He will continue in this feeling, however, only if it receives encouragement, whether this emanates from the behavior of those around him, or whether it has been inculcated before the accident by such unwise utterances as that of the British Minister of Labor.

If, on the other hand, the soldier believes that in the vast majority of instances a concussion by a shell is not necessarily of greater significance than the seeing of stars after a knock-down blow in boxing or a fall on the ice, he very quickly allows himself to be persuaded by his regimental doctor that there is nothing serious the matter, and returns to duty at the proper time without further preoccupation. If, however, he is allowed to rest for some days in the belief that he may be seriously damaged, and especially if he is passed from pillar to post and undergoes frequent medical examinations before he is dealt with as a *pithiatic*, he will have already persuaded himself that he must be a very sick man and that the doctor who begins to treat him by persuasion does not understand his case and is unnecessarily harsh. The patient, feeling thus, resists treatment. When the doctor allows himself to be baffled the first time, the patient becomes more and more obstinate in his determination to stay sick. He becomes what is known as a *perseverator*, and can then be restored to efficiency only by intensive and highly skilled treatment.[4]

Proper Prophylaxis Against Fear

From several quarters the recommendation was made that these reactions could be best prevented by deliberate prophylactic instruction of the soldiery concerning the nature of so-called shell-shock in its different forms. *A priori*, to those not versed in psychopathology it might appear very specious to argue for the prevention of the unfortunate psychopathological consequences of explosions which have occurred in so many cases during the war. What more natural than to suppose that to be forewarned would be to be forearmed?

Proper consideration regarding the facts concerning hysteria shows the hollowness of these pretentions; for it is a well known fact, even to the teacher in an elementary school, that to place before a person any idea or argument is also to implant in his mind the possibility of its contradiction. For instance, to say to a child, "Do not be afraid," is immediately to induce in him the idea that there is occasion for fear, something that he may not have in the least suspected before the warning was given. In this inductility the vast majority of adults are no better than children. Indeed, it is a human character. Hence, to give prospective soldiers systematic instruction regarding possible loss of nerve after explosions would simply be to exaggerate the import of a shellburst which does not wound. It would encourage preoccupation by the possibility of the occurrence of shell-shock whenever they went into action; the self-confidence of the individual would be destroyed, and the morale of the troop would deteriorate. Indecision and fear would take the place of dash and courage.

3. Williams, Tom A.: Management of Military Hysteria, Military Surgeon, November, 1919.

4 This subject will be fully treated in the author's forthcoming book on "Disorders of the Nervous System in Warfare."

On the contrary, the best preventive of demoralization by explosives would be to ignore the whole subject, never to let them hear of shocking by shells, if that were possible; or, at all events, to pay the minimum of attention to it, never to discuss it nor read about it, for in no subject to a greater degree than in psychology is the "little knowledge" so dangerous a thing. Misapprehensions, misinterpretations are inevitable. Every neurologist of experience knows how easily even patients of the ostensibly intelligent class, and perhaps intelligent in other matters, make mistakes about the psycho-pathology of their disorder, even when dealt with individually and intensively. Individual and intensive dealing with the soldiery is impossible. They have to be dealt with in groups, even in the case of the officers. There are not enough neurologists with clear conceptions of modern psychological data to instruct individually even the colonels and majors of the army. It follows that prophylaxis by instruction would be a futile measure even if the command were imprudent enough to undertake it.

Complete Dominance During Action

Psychology teaches us that a person dominated by one emotion cannot have a conflicting feeling at the same time. The lovesick swain has little appetite for food. The football player works up to an intense lust of victory, and feels no fear for his body. Indeed, he often fails to feel severe pain inflicted during the game. The best spirit to encourage in the soldiers is not the negative one that they cannot be attacked by shell-shock, but the positive one of desire to gain their objective, even if this desire has to be fomented by hatred of the enemy. The complete dominance during action by a desire to win at all costs, similar to that shown in the football player, is the spirit to aim at during attacks. In proportion as this rules among the men, there will be less room for pusillanimity or apprehension of shell-shock. The man knocked down by a shell will tend to immediately get up and join the rush just as a football player who falls.

But one will object that cases will occur, as they have occurred in the other armies, in spite of anything. Of course this is so; but, in the first place, it is quite certain that their abundance is inversely proportional to the healthy skepticism regarding their inevitableness; and, in the second place, that they are more abundant in proportion as the medical officers show vacillation and lack promptitude in the manner of dealing with them.

What was known before the war to some, since the war stares everyone in the face, namely, that the resistance of a hysterical patient is very slight if he is dealt with during the formative period of his disorder, and that the recalcitrance of the symptoms increases progressively with their duration. Hence, the medical officer of the first casualty station, who has the power to demonstrate rapidly and powerfully to the hysterical soldier that he is entirely mistaken in his view that his condition is serious, and deals with him on the spot firmly though encouragingly, finds that he has to send very few cases behind the lines in consequence of pithiatic disturbances due to explosions. The moral effect of the patient's recital to his fellows after the attack of how quickly his doctor restored him and sent him back to the line is invaluable. In the other case, the moral effect of explosions is disastrous to the morale of the whole company in the next attack and even before it.

Of course, it is necessary that the regimental doctor shall be able to distinguish these cases and be reasonably free from mistakes. It does not require great neurological erudition to do so. The absence of unconsciousness, the presence of the normal reflexes, and the absence of visible wound should make him immediately skeptical as to the validity of any neurological symptoms complained of. Doctors inexperienced in neurology will, of course, make mistakes and send some men back to the lines who in reality are not fit to go on account of the severe disturbance of the emotions which really should necessitate evacuation. But a few mistakes of this kind are a lesser evil than the destruction of the morale of a whole army, especially as these mistakes are readily rectified by less rapid examination after the stress of the attack is over, when it is a very simple matter to send the patients to the nearest neurological center for diagnosis.[2]

Present Strength of Medical Corps

The office of the Surgeon General states that the commissioned strength of the Medical, Dental, Sanitary, and Veterinary Corps on active duty is 3,206, in addition to which there are 7,768 officers in the Reserve Corps, making a total of 10,974.

THE MEDICAL PROFESSION IN KENTUCKY

The health code of Kentucky is a victory for the medical profession of the state in its fight for advancement in the protection of public health, and organization of County Health Departments as provided in the new law will now proceed under the direction of the whole medical profession. Fulton County is first in providing a whole-time health officer at the maximum salary provided by law, and some twenty other counties have the step under consideration. Close cooperation with the State Board of Health is assured, and the collective responsibility of the medical profession should assure the efficiency of the health work.

SIMPLE GOITER—A PUBLIC HEALTH PROBLEM

By CAREY P. McCORD, M.D., and ROBERT C. WALKER, M.D., Department of Industrial Medicine and Public Health, University of Cincinnati

Simple goiter becomes a proper matter for public health considerations because of its enormous incidence and because of the practicability of its control by general measures.

Readily applied remedies of proved efficacy and of sufficiently low cost have been devised for its control. These measures, while not fully standardized, have been demonstrated to be harmless and simple of administration.

The school age coincides with the age of the highest incidence of goiter, and the public and high school systems afford a splendid mechanism for carrying out the work.

"SIMPLE GOITER is probably the easiest of all known diseases to prevent." The prophylactic measures instituted by Marine and Kimball have yielded such results as to lead to the statement quoted. In widespread areas of the country the incidence of simple goiter is such as to involve 56 per cent of all women within certain age limits. Among men the incidence, although much less, is of such frequency as to be of definite significance. This occurrence of goiter is unnecessary in that it is probably wholly preventable through procedures carried out at trivial cost, and attended by no risks or inconveniences.

Any condition definitely disfiguring, and in many instances attended by disturbing manifestations, which involves hundreds of thousands of young women, demands systematic public health consideration. Particularly is this condition a practical public health problem through the necessity of applying generally, in goiter areas, the simple prophylactic measures so successfully carried out by Marine and Kimball in Akron and in other cities in Ohio.

Endemic or Simple Goiter

Simple goiter is the commonly encountered "big neck," known to all the public in goiter districts. This form of thyroid enlargement embraces the types formerly designated as endemic, epidemic, and sporadic goiter. It also includes the forms designated in terms of periodicity as fetal goiter, goiter of adolescence, goiter of pregnancy, and, in anatomical terms, such forms as non-toxic, parenchymatous goiter, colloidal goiter, cystic goiter, etc. In general, it is sufficient to note that simple goiter includes all cases of thyroid enlargement except toxic goiter, exophthalmic goiter, thyroiditis, and true thyroid neoplasms.

Simple goiter is a deficiency disease characterized by a non-inflammatory enlargement of the thyroid gland, unassociated in the greater number of occurrences by any marked functional disturbances. To the patient a simple goiter is a matter of concern usually for one or more of the following reasons: (1) The goiter is disfiguring; (2) the goiter, from its size or peculiar location, brings about symptoms from mechanical pressure on neighboring tissues; (3) constitutional disturbances actually attributable to the trivial thyroid deficiency, such as apathy, chilliness, constipation, asthenia are produced, or symptoms attributable to the mental state incident to apprehension over the enlarged neck.

The Prevalence of Goiter

The extent to which goiter prevails throughout the world is seldom appreciated. Few countries appear to be entirely free from it. In various portions of the globe there exist well defined extensive goiterous areas in which the large majority of the people are affected. Notable among these districts are portions of India, Switzerland, and Brazil. However, in countries that are not definitely looked upon as goiterous districts the incidence of simple goiter is remarkable. In France it was computed in 1874 that no less than one-half million persons presented simple goiters. In England and Scotland simple goiter is equally prevalent, especially in small areas such as Derbyshire and Nithsdale. The terms "Derbyshire neck" and "Nithsdale neck" are in common use among the public, and are indicative of their recognition of the prevalence of goiter in these two localities.

In the United States the entire Great Lakes Basin is regarded as a definite goiterous area. However, as the results of careful study and extensive

surveys accrue, it is at once in evidence that simple goiter is widely distributed over many other portions of the country. It is difficult to estimate the number of persons afflicted and definitely to delineate the sections of the United States wherein goiter prevails. Numerous isolated investigations have been made, and from these it is possible to evaluate the significance and the prevalence of simple goiter in approximate terms for the country as a whole. The entire Great Lakes Basin may be regarded as one large goiter district within which are numerous other centers, wherein the prevalence of goiter is even greater than for the area as a whole. Holder has described centers in Montana, Dakota, Mississippi, and, also, in the vicinity of the Rocky Mountains. Marine finds the disease widely disseminated along the Great Lakes, both among humans and animals, especially among sheep and dog. According to him, 90 per cent of the street dogs of Cleveland are goiterous. Other centers have been described by Munson among the Indians; by Dock in Michigan; by Ashmead in Pennsylvania; in Montreal, Buffalo, Detroit, Cleveland, Islands of Lake Erie, Oregon, and in Seattle. According to Bircher, goiter is common in the states of New York, Ohio, Virginia, Michigan, Kentucky, Tennessee, Maine, Vermont, Connecticut, Massachusetts, and New Hampshire. In general, the Atlantic states, with the exception of the western portions of New York and Pennsylvania, and the Gulf States, not including Texas, present a lower incidence of simple goiter than the Middle West and the western states. In the latter, wherever careful and extensive surveys are made, it is regularly established that simple goiter exists with such frequency, notably among young women, as to warrant public health concern.

The Frequency of Goiter

A study of the public school population affords the most accurate data of the frequency of goiter, inasmuch as the public school inclusive ages cover the period of its greatest incidence. The third decade, twenty to thirty, is the next period of greatest frequency. Marine and Kimball, in the City of Akron, Ohio, in April, 1917, examined 3,872 school girls between the fifth and twelfth grades inclusive. Of this number 2,184, or 57 per cent, were found to present simple goiter; 1,688, or 43 per cent, were found to be normal. All of the young young women examined were in the second decade of life. The frequency increased with the years of age, being 41 per cent, for the years of 10 to 12, inclusive, and 60 per cent for the years of 18 to 20. It is noteworthy that goiter is so infrequent among young males that it was not made a matter of study by Marine and Kimball in their Akron survey. In the second decade, goiter occurs about six times more frequently among girls than among boys. This sex predisposition is not fully accounted for, but probably finds origin from the fact that in the phylogenetic development of the thyroid gland this organ has always been more especially associated with the physiologic processes of the female, particularly with female generative function. In West Virginia, Clark examined 13,836 school children of 11 counties, in 1913, and found 1,234 cases of goiter, which is 9 per cent of the number examined. In Virginia the same worker examined 6,432 school children in nine counties and found 817 cases of goiter, which is 12 per cent of the number examined. In Huntington, W. Va., 50 per cent of the girl students were found to be affected. In Virginia, less than one-tenth of 1 per cent of the goiters found were among boys. In Europe, an even higher incidence among school children is reported. In Bavaria, the statistics of Schittenhelm and Weichardt indicate incidence as high as 77 and 89 per cent of the total school population.

The report by Hall of 3,339 students at the University of Washington is indicative of the frequency of goiter in the Northwestern states. This writer examined 2,086 men of the average age of 20 years and 5 months, and found that 18 per cent presented enlarged thyroid glands. Of the 1,253 women examined, with an average age of 19 years and 3 months, 31 per cent presented enlarged thyroid glands. Although these figures demonstrate the widespread prevalence of goiter in the northwestern states, they probably do not afford the maximum figures in that the greatest frequency occurs during the public school age rather than the university age. A certain percentage of enlargements existing at the time of puberty would have receded by the time of university age. Also it is known that simple goiter more frequently is encountered among the low types of individuals living under unsanitary conditions, who would not be found in large numbers enrolled in a university.

Olson, working in Chicago, made examinations of 606 women and 193 men with ages ranging from 18 to 60. Among the women, it was determined that 18 per cent presented enlarged thyroids, and 7 per cent of the men were found to be affected.

7. Hall, D. C.: The Prevalence of Goiter in the Northwest, Based on the Examination of 3,339 Students Entering the University of Washington, Northwest Med., 1914, n. s. vi, 189.

Smith, an Army surgeon, in 1918, examined 65,507 men of army age, 18 to 31, at Jefferson Barracks, and established an incidence of 1.63 per cent. The men examined were drawn from fifteen Mid-West states, including Texas. The highest incidence of goiter was observed in men from Oklahoma, where 38 per cent of 221 men examined presented goiter. The men from Texas presented goiters in 20 per cent of 141 men examined. Smith notes also that since compiling his statistics for fifteen states, exclusive of Idaho and Montana, recruits from these two states were examined and revealed a high percentage of goiter. Smith concludes that goiter is more common outside of the Great Lakes region than is usually considered, and that men are more frequently affected than reports would indicate. Kerr reports the occurrence of goiter among 21,182 troops at Camp Lewis, in Washington. These men were inducted into service from eleven states, comprising an area of approximately one-third of the United States. Of the number examined 21 per cent, or about 4,448, presented definite enlargement of the thyroid gland.

These several groups of data obtained by workers in various scattered localities are indicative of the existence of a high frequency of simple goiter among our young population, especially among young women.

No figures are available permitting any reliable estimation as to the total number of persons in this country, or any large portion of it, presenting varying degrees of this malady. An extension of Marine's figures obtained at Akron to apply to all within a school age in Ohio and other states of the Great Lakes Basin will naturally be only of approximate correctness. It is recognized that Akron, being nearer the Great Lakes district, will present a higher percentage of affected persons than will such cities as Cincinnati, situated at the periphery of the Great Lakes goiterous region; but even in such cities a high incidence of simple goiter may be noticed wherever groups of women are observed. With a full recognition of the gross inaccuracies entailed Marine's figures are extended to afford some basis of a conception of how significant simple goiter is as a public health problem.

There are in Ohio by the figures of the last census, 2,332,362 women; 432,851 are between the ages of 10 and 19 inclusive. This is the period of the greatest incidence of goiter, and is the age investigated by Marine. If the condition of the 56 per cent of involvement established in Akron obtained for the entire state of Ohio, 242,376 young women of the second decade would present goiter. At once it is to be emphasized that these figures apply to but one decade of one sex, and do not include the very high incidence of goiter in women of the third decade. Similar estimations for other states of the old Great Lakes Basin, and for other known goiter areas, yield a total figure of involvement that warrants earnest action. These figures become peculiarly pertinent in terms of the simplicity of the measures by which a continuation of this condition may be obviated.

Goiter in Animals

Goiter is not a disease confined to humans, but is found in large numbers among animals in goiter areas. It is perhaps an index of our comparative concern in human and animal welfare that goiter among animals has been the object of many practical prophylactic measures, whereas in the same district the occurrence of goiter among humans has been the object of scanty prophylactic consideration. The instances of the occurrence of goiter among animals here referred to are largely obtained from the publication of Marine. Among animals, as is true for humans, the greater number of goiters occur among the female. This is especially true of swine and sheep. Marine has already been quoted above to the effect that 90 per cent of the dogs of Cleveland are affected with goiter. The early days of the sheep industry in Michigan were found to be unprofitable in that a large percentage of the animals presented goiters. The young were many times "runts," failing to grow even when supplied suitable food, and yielding an unsatisfactory quality of wool. The abandonment of this industry was contemplated, but a fortunate discovery turned this industry into profitable channels. During the years of high frequency of goiter among sheep the salts fed these animals were obtained from a remote source. Coincident with the time of the contemplated abandonment of the sheep industry, but having no other connection with it, salt mines were opened up in the vicinity of Detroit. Shortly after the substitution of this locally obtained salt it was readily observable that the sheep so fed were better in every respect, the young were born free of goiter; they did not subsequently develop goiter, and were in all respects normal. Careful investigation established the fact that the locally supplied salt contained as an

impurity minute traces of iodin salts. The small quantity of iodin was adequate to meet the requirements of the sheep, and thus this condition in Michigan has been largely eliminated. In Montana, North Dakota, South Dakota, Washington, Minnesota, and portions of Canada, there are extensive areas in which practically all types of domestic animals present manifestations of hypothyroidism associated with enlarged thyroid. In Montana alone, G. E. Smith reports that about one million young pigs were lost annually on account of this disease. The condition was present at birth, the young pigs being born hairless and generally stunted. Many were dead at birth and few survived more than from twenty-four to thirty-six hours. The affected areas in some instances are sharply demarked. At times the district is confined to so small an area as a creek bottom one-half mile wide. Farmers have established that if their brood sows are moved out of these areas up into the hills a mile or two away, normal pigs may be born. Chemical examination of the thyroid glands of affected pigs determined that although the glands themselves were large, goiterous, the iodin content was extremely low in comparison with normal pigs. In general, the iodin content of the gland varied inversely with the degree of stuntedness of the animal's development. The addition of small quantities of iodin salts to the food of sows practically eliminated this condition among the sows so treated. In all instances normal pigs were born.

In goiterous regions not only are land animals subject to goiter, but fish as well. Seldom is goiter encountered in the native state of fish in streams; but under conditions of artificial propagation, such as those carried out by the Bureau of Fisheries, a disease known as thyroid carcinoma has been recognized for a long time. Only in recent years, however, has this condition been established as a simple goiter alike in many respects to the goiter of man and domestic animals observable in the same area. It has been noted that fish that developed goiter under artificial living conditions lost their goiters when placed in open streams. Also, it has been observed that the amount of goiter in any hatchery was in proportion to the uncleanliness and general lack of sanitation of the hatchery in which the fish propagated. So frequent and so disastrous was this condition at the time prior to its recognition as simple goiter rather than a true carcinoma, that fish culture in goiter areas was on the verge of being discontinued. Through the work of Marine and Lenhart both the nature of the disease was established and simple means were evolved for its eradication. In general these measures consisted of continued cleanliness of the fisheries, the supplying of food containing proper constituents, but particularly the addition of small traces of iodin or iodin salts to the living water of the fish. Wherever they have been instituted, these measures have eliminated goiter in fish.

The Cause of Simple Goiter

Consideration of the cause of simple goiter involves: (1) a precise exciting agency; and (2) conditions and factors that favor the development of goiter. No final statement may be made as to a precise causative factor. According to Crotti, St. Lager refers to 378 writers who offer 42 different theories as to the excitant, most of which are manifestly untenable. For a full consideration of the specific causes of goiter, reference should be made to the publications of McCarrison, Crotti, Marine, and Zueblin. The chief theories advanced center around either soil, water supply, microbic infection, or organic toxins. Precise evaluation of the various evidences offered does not permit of final acceptance of any single one of the four. Whatever be the specific cause, simple goiter may with some justification be regarded as a deficiency disease which tends to appear with greater frequency under conditions of living and working which can largely be controlled by proper hygienic and sanitary measures; such conditions are over-work, over-crowding, poor ventilation, bad water supply, lack of proper personal hygiene, the improper disposal of sewage, abnormal menstrual function, worry;—anything that makes undue demand upon the physiologic function of the thyroid contributes to the development of goiter.

The Prevention of Simple Goiter

"Simple goiter is probably the easiest of all known diseases to prevent." From the figures cited above it is evident that each year many new thousands of cases are developing. After development simple goiters are not readily amenable to treatment, only about 30 per cent subsiding under medical treatment. The usual history of the goiter is for it to develop about the time of puberty, slowly but progressively to increase in

size for a number of years, and to recede spontaneously at some time during the third decade. A great many, however, persist throughout life, and a few develop into true exophthalmic goiter. In definite goiter areas every young girl is a potential goiter victim. Whatever be the nature of the deficiency bringing about the goiter, it can be substituted for by making available to the body small quantities of iodin through the oral administration at rare intervals of iodin salts. For two cents a year any child may be saved the disfigurement and the physical and mental disturbances accompanying goiter. The necessity of obviating goiter because of its economic and sociological import was recognized so early as 1848, when a goiter commission was appointed by the Sardinian Government to investigate and report on the causes, treatment, and prevention of goiter. This example was followed in 1864 by the French Government. In 1908, Switzerland created a goiter commission and more recently Italy has done likewise.

Although the administration of the salts of iodin has long been associated with both the treatment and prophylaxis of goiter, both among humans and animals, not until the recent work of Marine and Kimball were systematic measures devised and instituted for the prevention of goiter in humans. Since this time these measures, without having come into any general recognition in this country, have been recommended to the Swiss Government for adoption as a national measure.

The incipiency of goiter in the great majority of cases occurs in the second decade, in the ages of from ten to twenty years, at which time the greater number of persons of such ages are in school. The school organization with the school physician, the school nurses, or the intelligent teacher, affords the best mechanism for the carrying out of the simple medical procedures entailed. Twice yearly, at six month intervals, iodin salts should be administered in small doses over a period of ten days.

Any iodin preparation suitable for oral administration will provide the necessary iodin requirement for the thyroid. Potassium and sodium salts of iodin are equally efficacious, which renders the sodium salt the medicament of choice because of its low cost. Because of the deliquescence of sodium iodid, it is impractical to make use of this material in capsule form. In whatever manner the iodin material is administered, it should be accompanied by careful educational measures, in order that the rationals of these procedures may become common knowledge to all, so that these measures may be continued in post-school life.

The details of the measures advocated and carried out by Marine and Kimball are as follows: The prophylactic work was limited to girls. A careful census was made of all girls between the fifth and twelfth grades, inclusive. A suitable card was devised on which was recorded the results of physical examination with particular reference to the condition of the thyroid. Particular care was exercised that no person presenting manifestations of exophthalmic goiter should be subjected to the harmful action that iodids have on this infrequently encountered type. Both the young women free from goiter and those presenting simple goiters were treated with sodium iodid. Large groups, with and without goiter, were untreated and served as the basis of reckoning the results of treatment. The doses used and the duration of treatment are probably in excess of actual iodin requirements, but because of the known harmlessness of the material used it was deemed expedient to provide an excess. Subsequent developments may establish that a single dose of the iodin material is sufficient. Two grams (30 grains) of sodium iodid, divided into 0.2 gram (3 grains) doses were given each school day to each pupil in the fifth, sixth, seventh, and eighth grades. Each pupil received 3 grains of the material each day for a period of ten days. For the ninth, tenth, eleventh, and twelfth grades, the daily dose was doubled under the same conditions. It was recommended that these amounts be administered twice annually, May and December being suggested as the most suitable months. The material may be given at the school under the supervision of teachers or nurses. Bottles of the sodium iodid solution were distributed to the several schools. The solution was so prepared that the suitable dose was dissolved in 5 cc. of water, which in turn may be measured out to the children in small graduated glasses, which are obtainable at low cost. It is pointed out that from 25 to 30 mg. of iodin saturates the normal thyroid gland and, inasmuch as approximately 1,700 mg. are available in the doses given, obviously the iodin requirements are fully provided for; in fact, it is reasonable to believe that in giving so large a dose a prodigious waste of the medicament takes place. Among the 4,415 girls under observation no harmful results arose, except in that 0.5 of 1 per cent developed an iodin rash, which is of only trivial import and which quickly disappeared upon the termination of the treatment. Such measures were carried out by Marine and Kimball first among 3,872 girls and, later, among the same group with an increase up to 4,415 girls, and the following results were obtained: of 283 girls having normal thyroids at the time of the inaugura-

tion of the treatment, not a girl developed an enlarged thyroid; 100 per cent remained normal. Of 996 pupils having normal thyroids at the outset, who did not take treatment, only 637 remained normal from April to November, 259, or 26 per cent, developing slight goiters. Of 428 women having small goiters at the time of the inauguration of treatment, in 33.5 per cent the goiters wholly disappeared under treatment, while of 769 women having small goiters who did not submit to treatment in only 1.2 per cent the enlargement spontaneously disappeared. In other words, these prophylactic measures have reduced, in Marine's observations, the normally high incidence of goiter to zero.

Summary

The prevalence of simple goiter described above is common to many portions of this entire country. Low cost and readily applied measures have been devised for the eradication of this condition. These measures, although not yet fully standardized and simplified, have been demonstrated to be harmless and practicable. The school age coincides with the age of the highest incidence of goiter. The public and high school systems afford a splendid mechanism for carrying out these measures. It is believed that faithful application of these measures by public health workers, school, and industrial physicians will go far in stamping out this widespread and distressing malady.

BACTERIOLOGISTS MEET IN BOSTON

The meeting of the Society of American Bacteriologists held in Boston December 30 and 31 covered problems of recent research on such subjects as pneumonia, chronic empyema, influenza, dysentery, arthritis, diphtheria toxin, and many other related topics. Dr Francis J. Blake, of the Rockefeller Institute, presented some views on the pathogenesis of lobar pneumonia, which may have important bearing on the treatment of the disease in the future. "The Routes of Infection of the Lung in Pneumonia," also an illustrated lecture, was presented by Dr. George H. Smith, of the Yale Medical School. In an exhaustive discussion of "What Is Influenza Bacillus?" Dr. T. M. Rivers, of the Johns Hopkins Hospital, declared that the only true influenza bacillus is the one first grown and described by Pfieffer in 1893.

Officers were elected as follows: Dr. Charles Krumwide, of the Research Laboratory of the New York Health Department, was elected president of the society in place of Dr S. C. Prescott, of Boston whose term expired. Dr. F. C. Harrison, president of the MacDonald College in Montreal, was elected vice-president; Dr. A. Parker Hitchens, of Indianapolis, was reëlected secretary-treasurer, and Dr. J. W. M. Bunker was chosen assistant secretary, a new position in the organization. New members of the council are Dr. F. P. Gay, professor of pathology and bacteriology at the University of California and Dr. C. G. Bull, professor of immunology at the Johns Hopkins School of Hygiene in Baltimore.

SERUM THERAPY IN PNEUMONIA

One of the fruitful fields in the development of studies in immunity is the practical application of its principles in establishing by artificial means a resistance to the toxins of the pneumococcus. The preparation of the vaccines is an exact science and the use of sera in properly selected cases of typed strains has commanded the attention of clinicians to a marked degree in recent months. With the perfection of technic it is hoped by the advocates of the procedure to find the means of combatting the dread disease, pneumonia. We present herewith the description of Robert W. Mackenna[1] of the toxic action of the pneumococcus.

The Production of Antibodies

"Once it was believed that an infectious disease used up some pabulum of food which it found in the patient's system; and, as it was supposed to destroy this pabulum, there was none left for a second attack of the disease to feed on; but now it is recognized that, whatever substances a disease may destroy in our blood, it enriches the blood by causing the prophylactic mechanisms of the body to elaborate protective agents. When a microorganism invades the human body, *pari passu* with the production of poisons or toxins whose effect may be lethal there are produced substances that are inimical to the growth of the germ. . . .

How Protective Organism Operates

"If a person become infected with pneumonia we have a striking example of how the protective mechanism in the body operates. Pneumonia is an acute inflammation of the lungs, and it is now known to be due to a microörganism. The germ invades the lungs and begins to multiply there. The earliest symptom of which the patient is conscious is usually a sensation of chilliness, followed by violent shivering. This is the first evidence of the protective mechanism in action.

Protective Mechanism

"The sensation of chilliness is due to a contraction of the blood vessels in the skin whereby as much blood as possible, and therefore all the available leukocytes may be hurried to the invaded part. The violent shivering, which is due to rapid and repeated contractions of muscle fibers throughout the body, is involuntary, but purposeful and protective, for active muscular exercise is the speediest means of increasing bodily heat. A temperature of 102° F., and over, is inimical to the growth of microörganisms, and the patient's temperature is rapidly elevated above that degree as the first step in the protective scheme.

Organisms Produce Poisons

"As the organisms grow they produce poisons or toxins which are thrown into the circulation, and which may have a deleterious effect on the muscle fibers of the heart, and the nerve ganglia which control its action. The heart already has a sufficient mechanical strain thrown upon it, as it requires extra power to maintain the circulation in a lung which is rapidly undergoing consolidation.

"But the protective functions of the body are at work, and are rapidly producing substances which are antagonistic to the toxins, and to the microörganisms which are the cause of the disease. These substances are known

[1] Mackenna, Robert W. The Adventure of Life, The Macmillan Co., New York, 1919, $1.25.

as antitoxins, and they unite chemically with the poisonous products of the organismal growth, and render them inert to the living tissues. What part of the antitoxin is not required to neutralize the toxin remains over to exert its effect on the germs,—an effect prejudicial to their further development, and therefore beneficial to the patient.

Toxin and Antitoxin

"The occurrence of what is known as the 'crisis' in pneumonia, when the temperature rapidly falls, the rapidity of the heart beats and the respiratory rate come down to something like normal, and the patient in the course of a few hours undergoes a marked change for the better, indicates the point at which the amount of antitoxin elaborated in the body exceeds the amount of toxin, and so can neutralize it.

"In pneumonia we are therefore witnesses of a race between the production of toxin and antitoxin; and if the heart can hold out while the contest is at its hottest, a point will be reached when the antitoxin will overpass the toxin, and the patient will recover. Observations of this kind have opened up an immense field of curative endeavor. Repeated small successive doses of artificially produced antitoxins can be administered until a state of tolerance is established in the patient toward the disease.

". . . All modern treatment founded on the administration of vaccines, antitoxins and antisera has been built up from the recognition of the protective mechanism existing latent in the body. . . . There is little doubt that all dwellers in cities are daily being immunized against various diseases by the continuous ingestion or inhalation of disease germs. . . . Civilization and acquired tolerance of disease proceed hand in hand."

AMERICAN SCIENTISTS MEET

The eighteenth of the convocation meetings inaugurated by the American Association for the Advancement of Science was held in St. Louis the week of December 20, 1919, to January 3, 1920. "Chemistry as It Is Taught" formed the subject of Alexander Smith's contribution. "The Message of the Biologist," and "The Relations of Psychology and Anthropology" were presented by William Patten and Ales Hrdlicka. Dr. C.-E. A. Winslow's paper[1] on "The Untilled Fields of Public Health" sounded a warning that the medical fraternity and scientists are "without defense and are practically powerless to combat" a possible recurrence of the influenza epidemic.

Dr. F. S. Lee made a plea for the larger use of scientific measures to increase, by proper use, the physical powers of workmen. "I am convinced," said he, "that the time is coming when all industries will have permanent staffs of physiologists to keep in tune and overhaul their human machinery, just as they now employ engineers and mechanics today. A maximum amount of work will thus be obtainable." Doctor Lee considers that efforts aimed merely to shorten the hours of labor are beside the mark if they do not include a scientific study of fatigue, and if they are not planned to better conditions for the workman.

Infectious Diseases Taking Recess

Warnings were issued that influenza, spinal meningitis, and infant paralysis have not been wiped out, but are merely "having a recess." Dr. Simon Flexner, president of the Association, explained that progress has been made in the fight against cancer and that "medical research is gradually getting into a position of strategic superiority" in its attack on this malady. He made reference to the work of Doctor Noguchi on a serum that may rid the human race of the scourge of yellow fever.

Sociological and psychological theses made an opening for the introduction of discussions of current events which led to a ruling that future sessions will bar all matters which have no direct connection with scientific research. The papers constitute a symposium of the most important work now under way, and their publication will be a direct contribution to scientific literature.

[1]This paper wil' appear in an early issue of MODERN MEDICINE.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

DR. CHRISTIAN R. HOLMES, MASTER BUILDER, MEDICAL STATESMAN

THE death of Dr. Christian R. Holmes, on January 9, was the signal for carrying the flag at half-mast on many hospitals and public buildings of the country, and leaves a void that can scarce ever be filled. Especially significant is his death to those of the profession and laity who think and act in social terms, who appreciate the sacrifice, the labors that go with conscientious, well earned community leadership.

Particularly impressive is his life reviewed in these hours when our democracy is under fire —when even strong men question the future and wonder whence the leadership will come to stem the despairing tide. To the faint heart let this life give courage.

Skilled in his surgical arts, honored by his *confrères*, revered by his patients, Dr. Holmes really first found himself when a dozen years ago he began his public career as the builder of the Cincinnati General Hospital. In making himself master of the intricate and complex problems of this great undertaking he found real self-expression. The urge of service to his city, his daring dreams of its future medical needs drove him on, despite all opposition; in fact, he seemed to gain strength through temporary failure. He never faltered, in any imposed duty, no matter what political or financial obstacles were placed in his way.

The late Christian R. Holmes, Cincinnati physician, who was a builder of the Cincinnati General Hospital.

It is unusual for men to avoid the temptations of ease and luxury that come with prominence, success, and wealth. Dr. Holmes took seriously the stewardship that was conferred upon him by these three possessions. He had the prescience to realize the joy that may come to anyone by reaching out beyond the narrow confines of any specialty in medicine. Much as he honored and enjoyed his professional work, excellent as was his technic, he realized that his energies, his creative faculties were better to be used elsewhere, in a broader field. Other hands, other brains could perhaps equally well do his former work. He preferred to use his powers to lead the profession and the people of Cincinnati to build better than they knew for the medical and surgical care of the present and future generations.

And thus by sheer devotion to his avocation, Dr. Holmes, who by professional tradition should have been an extremely narrow individualist, acquired the broadest viewpoint of medicine from its social aspect. Adequate hospital service for his community became and remained to his end a personal obligation.

Might we not here sense the broad opportunities for rendering great service afforded other members of the medical profession? If physicians could but realize their especial capacity for civic leadership, many who are now but half-

happy in the daily repetition of their professional tasks would break their bonds, develop a broader human understanding and relationship, add new zest to their old work, and through some community service make lasting impress upon the *zeitgeist* and leave a real heritage to the coming generations. Never in the history of medicine, which is at the turning of the way, was there greater need for such constructive leadership.

The creative energy of Dr. Holmes was unsatisfied by the completion of the hospital. It became immediately focused on the construction of a great medical college and faculty. Here again his zeal to acquire the best ideas in the arrangement of the structure, his infinite patience with detail, his endless quest for helpful conference, resulted in a plant that was excellent architecturally, mechanically, and physically.

As Dean of the Medical College he gave unstintingly of his time and boundless energy, never faltering, always optimistic, ever energizing. Of necessity this type of nature made mistakes that the cooler, dispassionate, less energetic, neutral type of individual would not make, but the final test lies in the works that he has left behind him. The new Department of Industrial Medicine and Public Health, initiated in the Medical College last spring, became his latest enthusiasm. Its success was recurrently on his mind during the months of his final illness. If it succeeds, it will be another expression of the remarkable broadening of his social concept of medicine.

Of him it may be said, "He has gone to the Great Beyond" from a great present. His memory will endure as Citizen Holmes, master builder, patriot, medical statesman, public servant.

EDITOR.

LOUIS I. HARRIS DEFINES POLICIES OF INDUSTRIAL HYGIENE BUREAUS

"Preventive public health medicine has in the past several years suffered from retarded development, despite the fact that our knowledge of methods for the prevention of disease has been greatly enriched," said Louis I. Harris, M.D., discussing the subject, "Industrial Hygiene," before the annual meeting of the Medical Society of the State of New York.

"In the last two decades, the application of this knowledge in public health administration has been fitful and sporadic," he declared. "State and municipal public health organizations are altogether too prone to concentrate upon some more or less narrow province of public health work, and to create a number of independent divisions without any well-knit, coherent, and harmonious program, which would unite them all in a broad and comprehensive campaign for the prevention of disease."

The significance of the steps taken to bring industrial diseases and working places more directly under the supervision of public health officers, Doctor Harris has pointed out in the following words:

"The work in industrial hygiene, which it has been the privilege of the writer to organize for the Department of Health of the City of New York, has, since 1915, when it was initiated, more clearly and definitely become the expression of a tendency to bring the intensive activities in the prevention and control of tuberculosis, venereal disease, and other communicable diseases, of occupational diseases and degenerative diseases, into closer union. The introduction of industrial hygiene has reacted on the formerly disjointed and unrelated activities of the Bureau of Preventable Diseases to produce harmony, and is tending increasingly to make the work of the nurses and physicians in each of these respective fields supplement and enhance the value of each division of work which is comprised in this union of activities."

One of the essentials in industrial hygiene is the reporting of occupational disease by private physicians and by institutions which care for the sick. These reports give a clue in practically every instance of the existence of industrial conditions which are a hazard to health and to life. Upon receipt of such information, a medical inspector is sent to investigate the factory in regard to all conditions which may directly, or indirectly be responsible for the disease. For instance, the report of cases of anthrax led to the investigation of shaving brush factories, the results being submitted to experts in the manufacture of brushes, in the hide and leather industry, and in related branches of the work before regulations were adopted by the Board of Health.

The need of competent, industrial hygienic experts furnishes the best possible reason why medical colleges should give great heed to this subject and should equip medical men, not only with a knowledge of occupational poisons, but prepare them to render preventive health service in this field and to recognize the injurious effects produced by defective ventilation, the presence of various kinds of dust, or conditions which produce degenerative diseases through undue muscular exertion, or through the effect of fatigue.

Child hygiene, which was acknowledged some years ago as a distinct phase of public health effort, and which should have been extended to include adolescent and adult hygiene, has, as a result of the failure of public health officials to establish the two last named as distinct branches of public health medicine, been singled out for special distinction. Human life is precious without regard to age, and the prevention of infant mortality and protection of child life should be accompanied by an equally intense and unrelenting campaign to prevent the causes of disease and death which operate during the period when the child is entering womanhood or manhood and during the subsequent period as well. Yet we can point to no public health defensive organization which is comparable to that of child hygiene bureaus. This must stand as a reproach until bureaus of adult hygiene are established and all persons, without regard to age, enjoy in fair measure the protection of public health agencies.

HEADS INDUSTRIAL RESEARCH

Dr. William H. Walker, for many years head of the Research Library of Applied Chemistry at the Massachusetts Institute of Technology, has been named as head of the Institute's new division of industrial cooperation and research. Doctor Walker was connected with the Institute for twenty-five years before the war, and during the war served as Colonel in the Chemical Warfare Service. He was in command of Englewood Arsenal, Maryland, and was awarded the Distinguished Service Medal.

HUMAN ENGINEERING—A NEW MEDICAL SPECIALTY

By FRANK LESLIE RECTOR, B.S., M.D., United States Public Health Service, Brooklyn, N. Y.

THE awakening conscience of the industrial world has brought to the fore many problems of human relations that were either not thought worthy of serious study on the part of the management or were disregarded for other, often selfish, reasons. In many establishments the worker was too often just a shop number, or a cog in the great pulsating machine of the organization with which he might happen to be identified. Such employees worked by the clock and frequently learned to watch the clock more closely than they did their work, with the result that interest lagged, production both in quality and quantity lessened, and a chasm of mutual indifference and mistrust gradually opened between them and the management. Relatively few efforts were made to span this chasm, or obliterate it by mutual understandings and sympathetic supervision and considerations for others. Help was plentiful and, as no great effort was made to determine the cost of separations, with the consequent replacements by green help, there was developed a class of workers who lacked the desire to make permanent industrial connections.

A New Evaluation Made

Then came the war, and the "work or fight" edict brought to many the realization that here was a vast army in no condition to fight in the front ranks, but who must be utilized to fill the depleted ranks of those who were chosen for this greatest of all work. Many problems had to be solved and obstacles overcome in order to mould this large and unwieldy force into an effective, productive unit. The spur of necessity for delivering materials so sorely needed in military work made it necessary to increase production by the quickest and easiest means available. This means usually took the form of increased wages but, as the desired results were not obtained by this method alone, it became necessary to foster the spirit of cooperation between management and men.

With the advent of peace it was realized that the supply of world labor had been dealt with disastrously as some twenty million able-bodied workers had been removed from the industrial sphere. This devastation, occurring principally among the industrial groups of Europe, presented an opportunity for the United States to grasp a larger portion of the world's commerce. To cope with this situation successfully, greater unit production became necessary. The close of hostilities saw an exodus of workers to their native land which produced a condition of possible shortage of labor as considered in connection with the probable restrictions on immigration that will be placed in force by this Government. The situation created has caused those in charge of industries to apply themselves seriously to the question of increasing production in order to take their proper place in the larger opportunities unfolding before them.

Cost of Labor Turnover

It was during the war that the enormous loss from labor turnover was realized and an earnest effort made to check it. It was found that increased wages exerted little influence. Employment departments were organized to deal with the matter by a selection of the applicant on the basis of previous training and efficiency. Health was seldom considered as having an influence upon the ability to hold a position.

This high turnover brought many industrial accidents in its wake, and these had to be taken care of. State compensation laws required that. It was then that the medical man was called into closer association with industry than ever before. A comparatively new field was opened to the profession, and some few of its members were quick to grasp the opportunity and to see the possibilities of what the industrial field held in store for them. The men of vision were few compared to the large number who took their work as a matter of course; but those few have placed an indelible stamp upon industrial medicine and have formed a solid basis upon which this special branch of medical practice will be built. Unlike most other medical specialties, this one is rooted in the principles of preventive medicine as it has to do with keeping the worker well, contented, and satisfied with his job. A contented and healthy worker can produce far more than a dissatisfied and sick worker, and industrial management is learning the simple lesson that it pays to make and keep a man well and happy.

To this new specialty, usually termed Industrial Medicine, I prefer to give another name, one that more clearly defines the real scope and possibilities of what the work offers, the name of Human Engineering; for it clearly covers fields usually thought far removed from that of medicine, but which I hope to show is closely asso-

ciated with the medical field when considered industrially.

The Field of Human Engineering

The field of activity of this work is limitless. It has been estimated that among the forty million industrial workers in the United States there are two million lost-time accidents yearly entailing a loss of time of more than one day each. Of this number, 750,000 sustain a disability of more than four weeks' duration. About 22,500 are killed, and from 15,000 to 18,000 more suffer permanent disability. This loss is estimated to be more than 18,000,000 man-days per year, or the working time of over 60,000 persons. Each industrial worker is sick on the average eight days per year which amounts to the time lost of more than a million working people for one year. The loss in wages is more than one million dollars per year, to say nothing of the loss in production, the cost of medical attention, and the cost to the community of the permanently disabled workers who cease to be self-supporting. There is no greater problem before the country today than this problem of caring for the industrial worker. There is no one in the country today that can better cope with this situation than the properly equipped industrial physician.

Not only must the industrial physician of the future rid himself of the designation of the "Company Doc" who took care only of what came his way, but he must be able to interpret industrial processes, understand the operation of mechanical appliances; size up the human requirements for filling a certain job; make scientific studies into the hazards of occupations; make certain that proper working conditions are provided for the industrial population; and interpret these findings in terms of increased production, decreased turnover, and healthier and happier workers. He should also be able to tie up the home, community, and industrial life so that each would bear its share of carrying forward the great commercial life of the nation.

The human engineer comes into intimate contact with four departments of an industry:—*viz.*, employment, safety, medicine, and welfare, if he is fulfilling the obligations of his position he must know intimately and well the workings of each branch of this industrial relations group. By making a physical examination of applicants for employment he exerts a direct influence upon the placing of workers. If he properly follows up accidents, he comes in contact with the safety department. Of course he dominates the medical department and, if he has the proper interest in the worker away from his factory job, he must be familiar with what is being done in the home and community life of the workman.

Let us look at some of the details of contact with these agencies within the plant. The human engineer will, first of all, be called upon to determine if an applicant who is fitted by training or otherwise for the job he seeks is physically capable of filling the position. To make an intelligent application of his physical findings he must familiarize himself with the different jobs in the plant, with the several steps in the manufacturing processes, and then formulate a set of standards with which the applicant must comply in order to fill the position to the best interests of both his employer and himself. A worker may be unsuited for a job by reason of physical defect of which he may be ignorant, by stature, temperament, age, education, or other reason. The human engineer will determine these conditions, as well as the mental attitude of the worker toward his work at the time of making the physical examination, and will be able to place the worker where he best fits into the scheme of the organization. Communicable diseases can also be detected at this time and their introduction into the plants prevented. Measures looking to the correction of such defects as flat feet, impaired vision and hearing, decayed teeth, and others of a similar nature can be instituted at the time of making the physical examination, so that the worker is able to approach his task in the best possible physical condition.

Without the physical examination to discover the defects of the applicant useful members of the industrial community are oftentimes denied employment. One of the big problems the human engineer can help to solve is that of placing the handicapped worker where his services can be of the greatest value to the industry. By so doing the economic independence of the worker is assured, his mental attitude is directed into right channels, and he becomes a community asset rather than a liability. By placing the worker to the best advantage the work of the employment department is lightened by reducing turnover, a thing always costly and to be avoided. The worker has also been made to feel that some one has his interests at heart in thus placing him in his work.

Surgical Care Plus

The human engineer's contact with the safety department usually begins when an accident case is brought to the dispensary for treatment. In addition to caring for the injury be makes an investigation as to how the accident occurred and in cooperation with the safety engineer, de-

termines ways and means to avoid recurrences of that and similar cases. He may find that the work is fatiguing, due to faulty posture, poor ventilation, or to bad lighting (which may be poor lighting or too brilliant lighting with the production of glare), or to other conditions susceptible of correction. These matters are all within the scope of the safety department to correct, but this department is seldom equipped to discover them and to associate them with the cause of the accident.

His researches will lead him to consider occupational poisonings when the processes suggest such possibilities. The physical re-examination of workers in hazardous occupations will result in the accumulation of scientific facts of known value with which to replace the oftentimes erroneous opinions now held regarding the dangers and hazards of certain occupations.

In addition to caring for the accidents that occur, the human engineer should repair the temporary defects of the workers which tend to reduce their effectiveness to a considerable extent. Many times workers report for duty with headaches, indigestion, beginning colds, and other seemingly trifling ailments which can be relieved or eliminated by prompt application of therapeutic measures. By this means a day's production can be added to the factory output, and the worker will have the added satisfaction of knowing that his small needs are cared for in a sympathetic manner. He will also appreciate the fact that there is someone to whom he can go for consultation and advice regarding such minor ailments as may develop in the course of the day's work. The prompt attention to minor accidents will prevent infections, which always result in much lost time, wages, and production.

Correlating Community Conditions

While making a thorough study of the human machine in its industrial surroundings, the human engineer will seek further light regarding the worker's home and community life. Here his contact with the welfare department begins, but should not end until home conditions have been investigated and the fact determined if they have had any influence upon the worker when he was injured. A sick member of the family may cause such uneasiness of mind of the worker that he will be careless and much below par in his work. The human engineer may also be able to determine if there is unsympathetic supervision over this man's work by the foreman. A domineering and overbearing foreman can do more to reduce output and breed discontent than almost any other factor in an organization.

The human engineer will not stop at treating the patient and removing the disabling cause, whether it be due to industrial or home life. There exists the opportunity of planting the seeds of preventive hygiene in the broad sense in the minds and hearts of those with whom he comes in daily contact. Here the great field of preventive and social medicine opens before him and he has unlimited opportunities of sowing the seeds of right living in this soil. Short and simple messages on home conditions, personal hygiene, proper food and clothing, proper habits of body and mind, and the sure penalty suffered from neglect of these matters, can be placed before the industrial worker with an influence that can be obtained in no other way.

The question of mutual benefit associations, old age pensions, recreational and amusement facilities, community hygiene and sanitation, especially improved milk and water supplies, sewage disposal, and related matters having a bearing upon the worker's surroundings or state of mind, all come within the scope of the activities of the human engineer, if he but applies himself to them in the proper relation. The more closely his industry dominates the community, the greater are his privileges and duties in community associations.

Organization and Statistics

This engineer must be an organizer and executive as well as a statistician, if he is to fulfill the highest purpose of his work. Careful records must be kept of turnover, accidents, illness, and absence, not of the plant in its entirety, but by departments and occupations; and these records must be correlated and analyzed so as to show where deficiencies lie and upon whose shoulders the responsibility for their correction rests.

From what has been said, it is evident that the position of this new member of the industrial community is an important one. He should be the administrative head of the industrial relations group of activities. His place as head of the medical department is assured by education, training, and experience. He should direct the work of the employment department, by reason of his knowledge of individual workers gained through physical examinations, by the requirements of the job, and by a knowledge of working conditions. He should control the safety work by his contact with accident cases and his knowledge of plant processes and hazards. He should supervise the work of the welfare department, by reason of the intimate contacts that have been established by dealing with workers in other departments and in their homes. Combine these duties with those

of the interpretation of factory records having a direct influence upon production, the opportunity for education along the lines of preventive medicine, and the influence he has in shaping the social and community life, and it must be conceded that the member of the medical profession who accomplishes these things is entitled to add the degree of Human Engineer.

THE EMERGENCY SERVICE OF THE J. I. CASE THRESHING MACHINE COMPANY

By JOHN E. KONNAK, Superintendent, Employees Benefit Association, Racine, Wis.

THE first emergency hospital at the J. I. Case Threshing Machine Company plant became a reality in 1907. This was enlarged from time to time until the present complete hospital was recently put into operation.

The present hospital consists of a dressing room, 15x25; an x-ray and examination room, 12x22; a rest room 10x12; a dark room, a store room, and a spacious waiting room. In addition there is on the same floor the office of the superintendent of the Employees' Benefit Association.

The hospital is done entirely in white. The floors are tile and the walls of the dressing room are finished in marble. The dressing room is equipped with modern surgical apparatus and the x-ray room contains a modern x-ray machine with fluoroscope accessories, a scale, blood pressure apparatus, and such other apparatus as is used for the various analyses. The light in the hospital on account of its many large windows is ideal, while the artificial lighting is perfect.

The hospital is under the able management of Nicholas B. Wagner, a graduate of Rush Medical College, who spends his entire time at the factory taking care of the injured men and advising the sick. He is assisted by two graduate surgical nurses.

Hospital Care for Minor Cases

In all accidents, no matter how slight, we insist that the employee must report to the hospital for treatment. We have long been convinced that it is the little things that become serious. The big things generally come to the hospital, while the men with the slight injuries usually wait until they become serious before reporting.

For the last three months prior to this report, August, September, and October, 1919, 2,436 injuries were treated at the hospital, classified as follows:

Lacerations	716
Eyes	669
Abrasions	462
Contusions	230
Slivers	122
Burns	94
Punctures	53
Emery grind wounds	40
Strains and sprains	23
Scalp wounds	19
Infections and boils	17
Fractures	6
Amputations of fingers	2
Redressings	3,225

Of these, the 90 which were disabling accidents caused a loss of 627 man days, an average of 7 days per accident.

In the case of permanent or partial disability requiring payment of compensation, such charge is made against the department where the man is injured. This puts the foreman on his mettle and encourages the use of safety devices and further avoidance of accidents.

Consultation Service Urged

Besides these injury cases there are sick calls at the hospital. Here again we believe that "a stitch in time saves nine." We encourage a man, when not feeling well, to come to the hospital and consult with the doctor. After an examination he is advised as to the best course to pursue. If his ailment is slight, he is given a prescription or medicine carried in stock at the hospital. This is given to him without charge. A world of good is accomplished in this way and many employees are saved from serious sickness. That the men take advantage of this service is shown by the fact that during the past three months there were 1,840 medical calls at the hospital.

Then we have a follow-up system where employees are reported sick. The doctor calls on them personally to see how they are getting along and gives them such advice as they may ask for. During the past three months 293 medical calls were made at the homes of employees.

Connected with the hospital, we have the Employees' Benefit Association of which 90 per cent of our employees are members. Every member of the association is given a thorough physical examination. Those who have defects are advised how to take care of themselves and a remedy is suggested to cure the defect.

The Employees' Benefit Association of the J. I. Case Threshing Machine Company was organized January 1, 1909, its object being to provide its members with a certain income when sick or when disabled by accident, occurring either on or off duty, and to pay to their families certain definite sums in case of death; to create and maintain a fund which shall belong to the employees, to be used in payment of benefits to them, and to cost them the least money possible in consideration of the benefits received.

The management is under a board of trustees, consisting of twelve members, six chosen by the employees who are members of the Association; members whose earnings equal or exceed $166.66 per month.

Contributions are 2 per cent of the member's monthly earnings; in other words, a member in Class 14 would earn $85 per month; 2 per cent of this would be $1.70, his monthly dues. If this member should be injured in the factory he would receive 2 per cent of his monthly earnings per day, or $1.70, from the time of injury until his return to work, not to exceed fifty-two weeks. If this member should be off long enough to draw state compensation, it would be paid to him in addition to the $1.70 per day. If this member were taken sick or met with an accident while

The emergency hospital of the J. I. Case Threshing Machine Company is equipped throughout with the most modern surgical appliances. Marble and tile construction lend to its beauty and to its perfect sanitation.

and an equal number chosen by the Board of Directors of the company. The Board of Trustees appoints the Superintendent of the Association who, under the direction of the Board of Trustees, has charge of all business of the Association.

All employees who apply for membership and conform to the regulations may become members of the Association. At present we have 4,000 employees of whom 90 per cent are members. There are twenty classes of members, numbered from 1 to 20. The highest class in which an employee may be a member is determined by his regular or usual pay. Class 1 is for employees having the lowest salary, while Class 20 is for

not on duty, he would receive 3 per cent of his monthly earnings per day, or $2.55, the benefits payable for a period not to exceed fifty-two weeks.

If this member should lose the sight of one eye, he would receive six months' wages, or $510, and state compensation. If he should lose the sight of both eyes, he would receive two years' wages, or $2,040, and state compensation. If he should lose one hand or foot, he would receive one year's wages, or $1,020; if two hands or feet, he would receive two years' wages, or $2,040, and state compensation. If he should die a natural death or meet with an accidental death while off duty, his beneficiary would receive one year's wages

or $1,020, and state compensation. If he meets with an accidental death while on duty, his beneficiary would receive two years' wages, or $2,040, together with state compensation.

The Employees' Benefit Association of the J. I. Case Threshing Machine Company was organized for the employees and is run by the employees. As to comparison of benefits afforded to members, we stand alone in the extent and character of service rendered.

RESTAURANT FACILITIES FOR SHIPYARD WORKERS

By FREDERICK S. CRUM, Assistant Statistician, The Prudential Insurance Company of America; and Statistician, Labor Requirements and Statistics Branch, U.S.S.B., E.F.C., Philadelphia*

EXTENSIVE and careful surveys and inquiries made preliminary to the preparation of the government pamphlet[1] published under the caption of this paper proved indisputably the urgent need for more adequate restaurant and lunch room facilities in industry. The good success obtained from the installation of such facilities sustaining but, what is of even greater importance, by their direct contribution to the health and industrial efficiency of the workers. Many employers have testified that "it pays in actual dollars and cents to supply a wholesome, nourishing meal to an underfed employee." They have discovered that "an anemic industrial army is

Fig. 1. The urgent need for restaurant and lunch room facilities by shipyard workers was met by the New York Shipbuilding Company in the provision of this building at Camden, N. J. This is the exterior view during a busy hour. (Photo by courtesy of New York Shipbuilding Company, Camden, N. J.)

for the benefit of shipyard workers leads to the publication of certain details for the managers of other industrial establishments who wish to undertake the task of making such provision.

The value of company restaurants has been demonstrated again and again. Their success is proved not merely by the fact that they are self-predestined to retreat and defeat," for its efficiency is dependent upon the quality and the quantity of their food supply. "In almost every instance where the experiment has been tried, its success has led to extension of the service."

The Metropolitan Life Insurance Company reported immediate and continuous benefit from the addition to the mid-day meal made possible through the installation of their lunch room. A small experiment of the kind by the National Cash

Register Company gave such noticeable results that an extension of the experiment was carried to notable proportions. The National Biscuit Company of New York consider that their restaurant has been a "notable investment." The American Sheet and Tin Plate Company, of Pittsburgh, now operates ten restaurants in their several plants, which they believe keep their workmen more healthy and contented. The Illinois Steel Company added to their general encomium of the plan the statement that it makes an essential contribution to industrial betterment and promotes good fellowship and interest in the place of employment.

Success Depends on Feeding

No one has successfully refuted Napoleon's statement that "An army travels on its stomach."

Fig. 2. This interior view shows the self-service plan of the New York Shipbuilding Company, Camden, N. J. (Photo by courtesy of New York Shipbuilding Company, Camden, N. J.)

If it is true that military success is dependent upon the proper feeding of the soldiers, it is equally true that if the best results are to be obtained from workers in the shipyards or other industrial plants, adequate provision must be made for satisfying their demands for food with the kind that is most suitable for them, and under conditions best calculated to keep them contented. The published report goes thoroughly into the subject, presenting sketches of cafeteria layouts which are regarded as most suitable for industrial plant and shipyard purposes. The sketches were delineated by Mr. Walter DeMordaunt, who at the time was architect of the Statistical Department of the Emergency Fleet Corporation, and these plans were of restaurants then in successful operation. Mr. DeMordaunt, however, was able to make certain additions through his knowledge as an architect and to suggest some very important and, what have proved to be practically useful, additions. Especial attention was devoted to health and sanitation in connection with cafeterias, and this was prepared under the direction of Lieut. Col. P. S. Deane, M.C., U.S.A., head of the Health and Sanitation Department of the Emergency Fleet Corporation. Accounting features of cafeteria management were reported upon by Mr. Gordon Wilson, who at the time was general auditor of the Emergency Fleet Corporation.

At the time these studies were made, the food purveying conditions in many of the shipyards and other industrial plants were little less than scandalous; either no facilities at all were available at or near the yards or plants, or the men

were compelled to patronize unsanitary lunch rooms, saloons, lunch wagons, etc. The average quality of the food was, to say the least, very unsatisfactory. On the other hand, some of the yards had as early as August, 1918, felt the need of better restaurant facilities. The data supplied in the published report for guidance and standardization in installation of equipment of this kind were gathered from those who had already met this particular need of their employees. General principles of economical and serviceable construction are discussed. The location of the kitchens and mess halls is important, and space requirements are governed by the exin an orderly line. The counters should be so constructed as to furnish the maximum protection to the food while making it accessible to the workmen. Self-service counters should carry a front rail on which trays can be slid along as they are being filled.

Ample space is required in the entrance and exit passages, and in the kitchen and in the mess halls. The proper dining room space is from eight and one-half to ten feet per person seated. The tables and seats should be as attractive as possible without being fancy. The tops of the tables should be of materials easily cleaned. A swinging type of window gives very much bet-

pedition with which the men need to be served, as well as by matters governing general utility. Questions of sanitation, ventilation have a special bearing in installation of this character, and need to be adapted according to special requirements.

Matters Important to Service

The cafeteria or self-service plan would appear to be best adapted to the requirements of most industries. The buildings should be convenient to the workers, not too far distant from the work places. The kitchen should occupy a central position. The location of all buildings should be such as to secure good lighting and ventilation. Railings or barriers should be placed in front of self-service counters, so that the men can be kept

ter possibilities of ventilation than the vertical opening.

Experience teaches that it is good economy to purchase high grade equipment to insure that it will stand rough usage from mechanical washing and stacking. Equipment manufacturers and distributors will usually be able to submit estimates if they are furnished with particulars as to the numbers to be catered to. The kitchen of an exceptionally well equipped industrial canteen for 280 persons at Leeds, Eng., contains the following utensils: One large gas stove with three ovens; one steam-heated hot closet and carving table for heating plates and dishes and keeping the food hot; one steamer with four compartments for steaming and boiling; one thirty gallon

steam-jacketed pan for soups; one ten gallon copper water-jacketed pan for milk, stewed fruit, porridge, etc.; a knife machine; a potato peeler; a bread cutter; a steam kettle; a whisking machine for batter; a mincing machine; large bins for storage; enamel bowls, jugs, and stew jars; substantial tinned steel bowls for baking, and ordinary kitchen and dining room crockery of white stone ware. This canteen has a staff of matron, cook, and four assistants.

In one of the large American shipyards the following equipment was designed for use in nine separate mess halls, in each of which an average of 1,000 men were fed per day: One refrigerator; one nine-foot steam table; two coffee urns; two hot water urns; three hundred trays; five hundred dinner plates; six hundred each of soup bowls, pie plates, knives, forks, and tea spoons; and one modern steam dish washing and drying apparatus.

Problems of Management

The final success of restaurant facilities becomes largely one of management and depends to a great extent upon the person directly responsible for the buying, preparing, and dispensing of the food; upon the maintenance of adequate service; and upon carrying out a high standard of cleanliness, sanitation, hygiene, and general attractiveness of the whole layout.

The success of the works restaurant depends upon whether or not certain essential requirements are met. They may be briefly summed up.

Convenient Location.—The restaurant must be convenient to the workmen.

Attractiveness.—It must be attractive, light, airy, well spaced, and with plain but neat, clean, and attractive equipment.

Prompt Service.—Service must be prompt. Slow service is certain to make the works restaurant a failure.

Hours.—The restaurant should be open at all hours when there are night shifts. Coffee, tea, cocoa, and milk should be obtainable at any time.

Food.—The food served should be of first class quality; fresh, properly prepared and cooked, appetizing, and of good variety.

Prices.—The price of the food to the workmen should be so low as merely to cover cost, or at most to provide only a small margin above cost. The price of any given meal or articles of food should be prominently displayed. This is essential for prompt and satisfactory service.

Payment for Food.—The method of payment for meals should be simple, preferably by ticket or check with the meal and payment of cash to cashier on exit. Tickets purchased in advance save the workmen from carrying much change in work clothes.

Management.—First and last the success or failure of the works restaurant is dependent upon the manager.

THE RELATION OF THE MEDICAL DEPARTMENT TO THE COMPANY

By HENRY WIREMAN COOK, M.D., Vice-President and Medical Director, Northwestern National Life Insurance Company, Minneapolis, Minn.*

THOUGH the composite nature of the life insurance business, with its financial side, its legal, mathematical, medical, and sales sides, is what gives to life insurance the charm and ever present novelty and interest, nevertheless, this also has the tendency, especially as a company grows larger, to develop specialists, each in his own line, who, crowded by the daily routine, do not rub closely enough with one another, and who too often tend to over-emphasize their particular angle without a comprehensive conception or appreciation of the business as a whole.

Profiting, not by sickness as does the medical profession, but by health and longevity, life insurance companies can sell the principles of health to the public with greater advantage than can any other business or profession.

It follows that the medical and actuarial departments of the life insurance company should be in sympathetic touch and understanding with all organized health activities.

The function of the medical department is paramount. The view of the clinician, tempered by a knowledge of insurance statistics, may rightly be counted as the basis of sound health education.

This tendency has led to the custom in the American Life Convention meetings of having representatives from specialists outside the section present their points of view, resulting in some very valuable discussions and a better mutual understanding. This interchange of viewpoints has naturally been most highly developed between the medical and actuarial sections, leading, in the case of the Actuarial Society and the Medical Directors' Association, to a joint meeting of the two sections. The principle of more closely correlating the different specialists in our business should be a daily or weekly ceremony of every home office, the frequency to depend somewhat on the size of the company, but to be held as often as consistent with the number of subjects pending for discussion, and with the exigencies and convenience of the daily routine.

The benefit to the company from the custom of having official conferences is beyond the individual or aggregate decisions arrived at; it is represented in large part by the resulting development of the official force themselves. The officers of a life insurance company are of widely different mental trend and temperament and have been influenced by divergent training and experience.

A man from any specialized training such as law or medicine could hardly find a better environment in which to broaden and develop than in the association of a life insurance official family, provided he is given the opportunity to supplement his own equipment and experience by that of his associates, and does not confine his attention and interest too narrowly to the routine of his own department.

Medical Office a Whole-Time Function

Too frequently in the past the association of the medically trained officer has been merely a few hours taken incidentally from his practice, during which time he gave a superficial opinion upon the risk, based entirely on a clinical medical experience, unmodified and uncorrected by insurance statistics, or by business experience. Under such conditions it is impossible for him not only to give the correct ruling from the technical point of view, but to control the selection, the use, and the organization of the medical examiners, or to gain that intimate relation with the other departments, especially with the agency organizations, which is so invaluable in determining a unified and enthusiastic *esprit de corps*.

The history of the development of the business of life insurance shows that the technical and professional elements were first merely associated in a consultant or advisory capacity,—the legal, mathematical, and medical,—but soon came to occupy a recognized and integral part. This development is often repeated in the individual company. Starting with merely a skeleton organization, in most part agency and accounting, the professional and technical elements are soon found so vital and so intimately concerned with each step of progress that they are made definite whole-time departments, from which time they

* Read before Legal Section, American Life Insurance Convention, Omaha, Neb., September 22, 1919.

should assume their normal place in guiding the development of the company. Just as a legal element is involved in almost every transaction of a life insurance company, and a well trained legal opinion is of constant application, so a medical department should offer a far wider service to the company than merely providing a personal medical opinion of the risks presented for selection.

It is out of place here to discuss the strictly technical medical and actuarial problems involved in medical selection, as much so as a detailed argument relative to the admissibility of certain evidence would be before the medical or actuarial sections. We must assume that on strictly technical questions each department of a company is qualified to give correct rulings, though such rulings are the more valuable as they are modified by a broadened practical experience. But it is in questions concerning the relation of the departments to each other and the company as a whole that we are mutually interested and, therefore, with a full appreciation of the essential part that legal opinion, statistical evidence, salesmanship, and business expediency play in the conduct, both of the medical department and the company as a whole, we venture a brief discussion of some possible and profitable functions of the medical department besides its primary one of technical medical decisions. In many companies there is knowledge and talent in the medical department that is not given opportunity for full expression and development, and which could be used both to the benefit of the company and of the department.

Relation to Employees

The initial selection of an employee should be largely a medical problem, and this medical element is to-day of increasing moment with the social tendency to place upon the employer, more and more, a permanent responsibility for the employee. The importance of a physical examination as a condition of employment is so well recognized to-day that argument in its behalf should not be necessary, especially in a meeting of life insurance men. Yet it is safe to assume that many companies in the Convention are still accepting employees without the approval of the medical department. Such a custom is increasingly dangerous, as now, when many firms are excluding sick and impaired applicants from employment, a firm which does not use such precaution is very apt to have applications from a larger and larger proportion of the physically and mentally impaired. That a lay inspection, however skilled and experienced, can determine an applicant's health and capacity for effective work is not possible. In the first place, a firm owes it to its other employees not to expose them unnecessarily to contagion. Cases with active tuberculosis often appear healthy to superficial observation, as also cases with syphilis. Employees with extensive pyorrhea are very objectionable as nearby working associates, and those with diseased tonsils and those subject to repeated colds or tonsillitis are sources of repeated infection which often runs through the entire office force.

In addition to contagion, which is the lesser problem, there is the question of physical and mental capacity. An employee with exophthalmic goiter, with neurasthenia or hysteria, or with such conditions as nephritis, diabetes, or high blood pressure, cannot ordinarily give adequate value. Controlled, alert, efficient mental processes are not ordinarily associated with these and many other diseases which might be mentioned. Furthermore, many of these cases are very subject to periods of indisposition, necessitating annoying and costly absences. Many such subnormal employees, especially women, require or think they require extended vacations and such adjustments are costly and difficult. No employee, and this holds just as true for an officer, should be accepted without satisfactory evidence of good health and approval by the medical department.

All business houses are considering some form of social service work among their employees. This generally is largely of a medical nature. A life insurance company is well equipped to give sound medical advice to its employees and to give attention to minor ailments. This can be extended as far as seems desirable in the direction of visiting nurses, additions to diet during convalescence, and so on. The medical department should also be in a position to give advice as to office hours, lighting, ventilation, or heating. A healthy office force goes a long way towards guaranteeing a contented, effective, and economical force. Periodic examination of employees should be offered as a valuable service, and might better be made compulsory.

Relations to Other Departments

The very large majority of American Life companies are now well organized, and the officers are concerned whole-heartedly in giving the best service of which they are capable. They are appreciative of the respective parts that each play in the success of the company, and are steadily approaching a unified attitude towards the company's problems.

It is this "company attitude" which determines the standing and reputation of the company with

the public, the insurance fraternity, and its own agency force. When the insistence on new business and rapid growth is excessive, the company becomes known as addicted to "high pressure" methods; technical and professional opinion is apt to be over-ridden by ill advised executive action, and the reputation and financial standing suffer. In other cases, ultra-conservative and over-technical decisions may prevail; action is hampered by excessive caution; delays and indecision retard progress and dampen enthusiasm.

Either extreme is equally prejudicial. The executive attitude must include a recognition of the scientific basis of the business, and the necessity for observing the restrictions which a reasonable application of scientific knowledge dictates, and to that end the medical director and the actuary must be loyally upheld in their decisions. On the other hand, the medical director and the actuary both must recognize that a life insurance company is not an endowed scientific research laboratory. It is a money-making proposition primarily, either for stockholders or for policy holders, and must conform to reasonable business standards. Fine technical decisions, for which it must be admitted we often have no very constant or definite basis, must not be expected to replace a broad business policy.

Between the medical and the actuarial departments particularly, there must be constant and cordial exchange of ideas and information. The clinician and the mathematician regard a risk from different viewpoints, the medical man tending to emphasize the individual characteristics, the statistician insisting upon a ruling based on a more or less arbitrary classification of the risk according to one or more specific features or impairments. These two viewpoints must be correlated in each correct decision. As each professional man becomes also an insurance official, the one a medical director, the other an actuary, they find no difficulty in reaching a compromise and a mutually intelligible position.

Relation to Policyholders and the Public

Here the medical department can do as much or more than any other department in determining a favorable attitude towards the company. Public opinion, after half a century, is beginning to realize the truth expressed in Gladstone's aphorism, "In the health of the people lies the strength of the nation." Individual and public health are obtaining interest and attention. A life insurance company should stand as a practical and potent exponent of the methods of preserving health and prolonging life. This is not only "good business," but it is a social obligation incurred through the exceptional opportunities in this direction offered to life insurance companies. The organization contains within itself medical and statistical knowledge bearing upon disease and its prevention, and has exceptional opportunities for publicity on such subjects through the agency force and the policy holders.

Profiting, not by sickness as does the medical profession, but by health and longevity, with the additional weight which successful business enterprise always carries, life insurance companies can advocate the principles of health hygiene to the public from a more advantageous standpoint than can any other business or profession.

Therefore the medical and the actuarial departments should be in sympathetic and understanding touch with all public health movements. The company should hold membership in the national public health associations, and cooperate with other organized efforts in this direction. The company and its officials can well afford the time to take leading parts in health movements in their own community.

The agency and policyholders' magazines and circulars should contain advice from the medical department on questions of personal and public health. Life insurance agents necessarily obtain a smattering of medical knowledge. It is the company's responsibility, through the medical department, to see that they can discuss intelligently and give sound advice on general health problems.

During the course of his work a life insurance agent gains an astounding amount of information about the ailments and indiscretions of his friends and neighbors. He should be in a position to use this knowledge wisely. An experienced, keen agent becomes something of a snap-shot diagnostician. He appreciates and can use advantageously correct medical information. He should know the general principles, for example, of antituberculosis work, of cancer control, the significance of high blood pressure, of albumin, of casts, of goiter, of unprotected hernia, or of chronic indigestion.

Whereas medical advice from a physician is oftentimes received with skepticism, it is astonishing how frequently it will obtain attention if offered by a business man or fellow layman. A convincing talker, the life insurance agent can be a very considerable factor in moulding opinion within his circle of influence, and the medical department should give him the facts necessary for effective propaganda.

Here one's ability, firmness, tact, and resourcefulness are tried perhaps as in no other human

relationship, and this is but natural when we consider the apparent conflict of interest, and the seriousness of the issues involved.

From the office point of view, the efficacy of the effort at a wise medical selection determines largely the profit to stockholders or, in a participating company, the dividend to policy holders, and, in fact, determines the ultimate solvency and persistency of the company.

From the agent's point of view, in the rejected case, which is the one he remembers, medical selection has deprived him and his family of a large portion of their month's income for which he feels he has worked and planned faithfully. Let us make no mistake about it; it is hard work and a notable accomplishment to get that name on the dotted line.

As has been stated, the difference in viewpoint simulates an apparent conflict of interest. Of course, the conflict is only apparent. The actual interest of each agent is identical with the interest of each official, and is in both cases success for the company, in its largest and truest sense.

It is noted by those on the inside that the very agent who at the moment of disappointment whole-heartedly curses medical selection and everything connected with it, is the very man who uses as his strongest argument the company's low net cost, and waxes eloquent over the low mortality and careful selection. He knows perfectly well that he would not sell questionable protection to his friends and customers in a company which accepted drunkards, or underwrote heart and kidney cases at standard rates; but it is hard to be logical when you are going through the painful process of separation from a hundred dollar check. It is a wonder that agents are as uniformly loyal and decent about it as they are.

The medical department must recognize the vital part played by the agency force in the company's growth and success. The individual agent must be treated as a reasonable business associate, his evidence for reconsideration of decision carefully reviewed, and, above all, he must be made to realize that a case is declined only as a last resource, with a full appreciation on the part of the medical department that only the accepted cases are profitable to the company, and that every rejected case means a financial loss. The object of medical selection should not be the lowest possible mortality experience; it should be rather to accept the largest proportion of risks submitted and at the same time obtain a favorable mortality percentage. With this object the method becomes not to reject every case about which there is the slightest question, but by educating the agency force and by the organization of a corps of loyal, efficient examiners, to eliminate the wastage and disappointment of a large percentage of rejected cases and accept the maximum proportion of applicants who, selected on the basis of the most reliable scientific and statistical data available, will produce a reasonable and favorable mortality experience.

In order to be successful, the medical department must reach and influence the agency force in as direct a way as possible. The agency bulletin has no more important function, and yet one often neglected, than to advise the agent in helpful cooperating with the company's medical selection. A well instructed and wise agent will eliminate a large proportion of undesirable risks during the initial stages of the interview. The book of instructions should be as specific and detailed as practicable, covering all of the more common impairments. Agency meetings and visits to the field are means of bringing about a thorough understanding, appreciation, and cooperation between these departments, and should be consistently utilized by the medical department.

To Determine a Favorable Mortality

In determining a favorable mortality for the company the medical examiner has been mentioned as having a fundamental relationship to the success of the company, the importance of which relationship is frequently overlooked or neglected. In closing, therefore, a word should be added on this relationship because it is so closely allied to one fundamental legal principle, the safeguarding of expert opinion and testimony from improper and partial influence. The legal department of the company, as no other, will realize that a witness or an expert is valueless if he is prejudiced or subject to pressure which would alter or determine his attitude on the case. For example, what lawyer would be willing to employ an old friend and family physician of the accused in testimony for the prosecution? In determining the fraudulency of a horse sale, who would employ a veterinary selected by or in business relations with the man accused of the fraudulent sale?

Many life insurance companies are exceedingly lax in applying these principles to the employment of medical opinion. When three or four physicians are appointed on equal basis in a town and the agent and the applicant are privileged to employ any one of them, it should be obvious to anyone, as it is to a legally trained mind, that that physician will ultimately get all the examinations who passes the most cases, and that the physician who takes time and interest to discover existing impairments will soon have no appli-

cants from that company upon whom to exercise his skill. In other words, by giving the agent and the applicant the choice of examiners, you are putting a premium on dishonest or careless work. It cannot be too strongly emphasized that under such a system it is impossible to develop a loyal, interested corps of the best physicians available. A physician must be appointed in each town who is the first choice of the company for all examinations in that district when he is available. He then represents the company in rendering his testimony. If he is selected by the agent or the applicant, he will inevitably come to represent them versus the company.

Where Responsibility Attaches

It should be made plain that in this it is not implied that the agent is dishonest. The rules for selection are the responsibility of the company, not of the agent. He would be quixotic beyond normal expectation if he selected the physician who detained his applicant half an hour instead of ten minutes, who reported "unimportant details," or who was too inclined to discover albumin or heart murmur. If the company is satisfied to accept prejudiced testimony, can he be expected to insist on a technicality which will cost him a commission? This is a question which goes to the very roots of the success of the company. It is absolutely essential that the medical examiner should be loyally maintained, irrespective of the agent's or the applicant's preference, provided he is competent and reliable. A company which changes examiners on the agent's or the applicant's request or whim, except on sufficient and proved grounds of undesirability, cannot expect loyal service from the physicians in its employ, and it will not obtain such service.

In this ruling as in so many others, the legal department will be in a position to lend its trained advice and effective support. A loyal and unwavering adherence to the chief examiner throughout a period of good service will do more than any other one thing to render the examination blank trustworthy and to assure impartial evidence of insurability. As this evidence is the basis of the insurance contract, it must be kept divorced from prejudiced, harmful influence.

COMPENDIUM OF NECESSARY CONSTANTS

The National Research Council in America, supported by private funds, will have for its special task or purpose that of ascertaining exactly what scientific knowledge and resources are possessed by the Nation, and what are the means for increasing this knowledge. It purposes to compile and issue, with the cooperation of the American Chemical Society and the American Physical Society, a critical American Compendium of chemical and physical constants which shall be up-to-date and correct. The university and research laboratories of the country will be asked to aid in supplying the needed facts, and business and industrial concerns whose work is based on applied chemistry and physics will be asked to supply a list of all the constants required in their work. The investigations of the Council will attempt to determine such constants and include them in the compendium.

AN ERA OF PREVENTIVE MEDICINE

By Our London Correspondent

All signs go to show that in civilized countries an era of preventive medicine is coming in. In Great Britain, at any rate, the signs seem fairly evident. The creation of a Ministry of Health points in this direction, as the work of this governmental department will be chiefly concerned with the prevention of disease and its aim will be or should be to forward by every means in its power the promotion of good health among the general population. Allowing for the great importance of curative measures, it still stands as an undeniable fact that the paramount object in the fight against disease is prevention; to prevent the occurrence of communicable disease, and to prevent and restrict its spread; moreover, by providing hygenic and sanitary conditions in homes, schools, factories, and workshops to create and build up a healthy race. It is obvious that in this endeavor industrial hygiene and sanitation are factors of the first importance. A large proportion of the inhabitants of all countries and perhaps of Great Britain, in particular, is engaged in industrial work. If then a large and essential part of the population, the backbone, so to speak, is not healthy, the virus will spread, and the entire nation will deteriorate. However, there is no need to elaborate this point, as it is clearly apparent to every thoughtful person. The main intention of this letter is to sketch the situation as regards industrial hygiene and sanitation in Great Britain.

It has been an outstanding characteristic of the English speaking stock that its members have depended more upon individual than upon concerted effort. This inborn trait, and the consequent tendency to under-organization of the British nation, were manifested plainly during the war. But this defect is less obtrusive in the Public Health Service than in any other direction. The sewerage, drainage, and water systems are surpassed by no nation. The State has built up a vast but not coordinated organization for the purpose of checking communicable diseases, and has been eminently successful in so doing.

The Public Health Service exercises a strict and expert supervision over the future British subject from the time of birth to death. The individual is personally looked after and, if necessary, medically cared for when young. The school and factory and workshop are inspected according to the provisions in laws which have been carefully drawn up. If employed in an unhealthy trade the dangers to health are reduced to a minimum. If an accident is met with or sickness occurs, aid is given to provide professional attendance and medicine, and it is only when death comes and the mortal remains are buried or cremated in accordance with certain regulations that the interest of the State in the citizen ceases. The Public Health Service does considerably more than this for the Nation, and, in fact, the State has surrounded the population with sanitary safeguards of every description. It is superfluous to say that the effect of these far reaching activities has been entirely to rid the country of some deadly epidemic diseases and greatly to curtail the scope

of others. While the efforts of this loosely linked Public Health Service have been marked by the expenditure of much zeal and energy, and, in the main, have been highly successful, it is felt that if more coordination existed between the various bodies which exercise authority with regard to public health matters, the results would be even more striking.

It would seem that the welding together or centralizing of these bodies should come within the province of the Ministry of Health. Sir George Newman, the chief medical officer of the Ministry, in his memorandum entitled "An Outline of the Practice of Preventive Medicine" addressed to the Minister of Health and published recently, turns the searchlight of his views into every nook and cranny where the least suspicion exists that preventive medicine can be rendered operative in promoting the public health. Naturally, such a microscopic survey includes industrial hygiene; but in present circumstances the Ministry of Health cannot be expected to carry its avowed policies into effect. Some time must elapse before this is possible. The housing problem is the most insistent and the one with which Dr. Addison, the Minister of Health has pledged himself to grapple forthwith. It remains only to be said that the Ministry of Health seems to provide the logical means whereby the numerous bodies which now regulate the public health machinery of this country may be coordinated and centralized, if general and authoritative opinion decide that such a course is judicious and desirable.

I shall now proceed to present things as they are and describe briefly the manner in which public health matters are arranged in Great Britain.

Complexity of Public Health Administration

The Public Health Services of Great Britain are administered centrally by twelve, or thereabouts, independent and uncoordinated departments, boards and councils, and, locally, by nearly as many local authorities. The one of this number which is concerned with industrial hygiene and sanitation is the Home Office. This Office supervises sanitary conditions in factories, controls dangerous trades, and appoints medical referees and certifying factory surgeons under the Workmen's Compensation Acts. Generally speaking, factories may be defined as places in which mechanical power is used. As remarked, factories are inspected by Home Office inspectors. Workshops may be defined as places in which mechanical power is not used and, so far as sanitation is concerned, are supervised by officers of the local sanitary authorities. There are, however, a large number of non-textile factories which are controlled by the Home Secretary, whether mechanical power is employed in them or not. It can be stated that the multiplication of bodies whose duty it is to deal with public health affairs is a result of the piecemeal way in which these affairs have been arranged in Great Britain. Except for the general sanitary services, the needs of the country as a whole have never been provided for, but only for isolated groups.

Every factory must be kept clean and well ventilated and must not be over-crowded. A factory or workshop is considered over-crowded if there are less than 250 cubic feet of space per head, and less than 400 cubic feet if over-time is being worked. Every adequate measure must be taken for securing and maintaining a reasonable temperature in each room in which any person is employed, but the measures so taken must not interfere with the purity of the air of the room. Very stringent regulations are in force as to the provision of sanitary conveniences. Every local authority is required to keep a register of the workshops within its districts, and the factory inspector is required to forward to a local authority any notice received by him of the commencement of any workshop within the district of such authority. The menace of dangerous and unhealthy trades is minimized by every device that human ingenuity supplemented by medical knowledge can suggest. The Secretary of State, who is the head of the Home Office, has the power to make regulations in respect to any dangerous or unhealthy trade, such regulations requiring the adoption of special precautionary measures as regards cleanliness, ventilation, or extraction of dust. The law as regards retail bakehouses is administered by sanitary authorities and is very strict. Laundries in which steam or water or other mechanical power is used are classed as factories. All other laundries are workshops. These regulations are enforced without fear or favor and, in spite of the divided authority industrial hygiene and sanitation, are at a fairly high standard in Great Britain.

It cannot be disputed that many improvements are needed, and especially in the construction and situation of factories and workshops. Unlike America, England has been and still is to some extent conservative. Most of the factories are located in the heart of busy industrial centers in a smoke laden atmosphere. Many of the buildings are old and difficult to maintain in a satisfactory hygienic and sanitary condition. Being frequently, perhaps more often than not, surrounded by other buildings, adequate ventilation is not easy to secure; while in a moist, dirt-laden atmosphere pure air is practically unattainable. British factory laws are excellent and well enforced, but physical reasons tend greatly to restrict their hygienic value. One remedy, although a drastic one, is to scrap many of the existing factories and erect new ones outside the cities. This movement resolves itself into a question of transport and transit which is another hard problem to solve nowadays. American factories and also Canadian factories, as a rule, are superior in construction, in labor saving devices, in sanitary equipment, and in situation to those of Great Britain. The factories of many of the Lake cities of Toronto, for instance, are for the most part located outside the town, and are beautiful picturesque buildings, which do not bear even a remote resemblance to the dingy, squalid, barrack-like looking buildings which pass for factories in the "Black Country" of England, for example.

Report of Chief Inspector of Factories

I have before me at the present time this annual report, and it provides instructive and even fascinating reading. It is of engrossing interest, and, unlike most dry as dust reports, it is a human document. It shows how the war quickened concern in the welfare of the industrial worker. New orders have been brought into vogue, and the old ones have been broadened and are more strictly enforced than ever before. The shortening of the hours of work, the researches on fatigue by eminent scientific men, the question of suitable food, have been so dwelt upon in the American medical press during the past two or three years that a recapitulation would be a mere weariness of the flesh. Suffice it to say that this far sighted and beneficient policy has borne the best fruits and that shorter hours of work have been shown to be better for employer and employee. Under the Act of 1916 orders have been made applicable to certain industries, and others are under consideration calling for arrangements for preparing or heating or taking meals; the supply of drinking water;

accommodations for clothing; the supply of protective clothing; facilities for washing, and for sitting in workrooms; ambulance and first aid arrangements. These orders are being supplemented and explained by pamphlets giving detailed advice.

It is not alone, nor even chiefly due to the enforcement of orders and compulsory requirements that steady progress is made. There must be sympathy, good feeling, and hearty cooperation between employers and employed if the best results are to be attained. Joint Industrial Councils have been established and steps have been taken by a Factories and Workshops' Inspection Department to get into touch with each Council at one of its early meetings to bring before it those matters with which the Department is concerned; that is, the health, safety, and welfare of the workers, and to urge its cooperation, not only in carrying out statutory requirements but in considering and bringing about future improvements.

Introduction of Labor Saving Devices

One of the most striking differences between the equipment of an American and a British factory is the great preponderance of labor saving devices in the former. In fact, it was only by the employment of such devices that American industries were able to hold their own in the markets of the world in competition with the cheap labor of Europe. The war has changed all this, and now British is nearly as costly as American labor. Therefore, if labor saving devices are not introduced into British factories, their chances of equalling the output of American factories in quality or quantity will be small indeed. Although the economic side of the question is not directly a phase of industrial hygiene, it is closely interwoven with that of hygiene. Both employer and worker now recognize that the introduction of labor saving devices increases output, reduces the cost of production and the risk of accidents, and tends to better health. This point of view has been emphasized by the advent of women into industries where their limited physical powers rendered them at a disadvantage as compared to men. Thus an extensive introduction of labor saving devices has been taking place in the factories of Great Britain, and a still more wide introduction may be anticipated in the future.

Welfare in Factories and Workshops

One of the most valuable chapters of the Report is that contributed by Miss A. M. Anderson, principal lady inspector of factories. Miss Anderson deals chiefly with the subject of personal hygiene, a matter which up to a recent date has been overlooked and overshadowed by the more obviously ambitious schemes for promoting public health. At the present time with the new conceptions as to the manner in which many infections are communicated, *viz.*, by transmission from individual to individual, it has dawned upon the advocates of preventive medicine, that personal hygiene is perhaps the most important factor of all in warding off disease and checking its spread. Cleanliness is next to godliness, and the conditions produced by the war in factories brought this vital truth home as it had never been brought home before.

Up to the time of the war a certain amount of dirt in some factories was looked upon as inseparable from the work in which the employees were engaged. If it was dirty trade, kismet, it had to be a dirty trade, and no efforts were made to provide facilities for washing. The war has altered these conditions for the better and an inspector states in the report that the extension of ample facilities for washing, from clean trades to the more dirty, is beginning to appear. The factory must be kept as clean as possible; but the question of personal hygiene is of even greater importance and bulks larger in the maintenance of industrial hygiene than any other one phase.

This letter has outlined in a somewhat discursive manner a few salient features of industrial hygiene and sanitation. The subject is a big one and it is not so much a question of finding material to discuss as of selecting that of the greatest value and interest to American readers.

In future letters various matters related to industrial hygiene and medicine will be discussed and handled more in detail. The point that it is especially desired to lay stress on is that it is to the advantage of all concerned that industrial hygiene should be brought to as high a pitch of perfection as is possible. It is better for the general public, the employer, and the employed. If the worker is not contented and healthy, his output fails in quality and quantity, and the entire nation suffers in pocket and in health. It is false economy to be unduly thrifty at the expense of the worker.

INDUSTRIAL MEDICINE AND SURGERY*

Dr. Mock's book marks the triumph of the industrial physician. Its contents suffice to prove that no other branch of the practice of medicine calls for such comprehensive, such profound, or such mobilized knowledge of the medical arts. It requires the highest ideal of general practice, plus preventive medicine, plus administrative ability. In the extensive bibliography at the end of this book, we do not find the name of any work covering the same ground.

There was a time, not so long ago, when physicians in this new specialty had to suffer from the dubious reputation of their predecessors, the "company doctors," a type of practitioner by no means extinct and, unfortunately, not a few of the industrial concerns who have gone to great pains to provide adequate installations for their medical services, have stultified their medical service by confiding the work to their former "company doctors" or, impelled by the habit of accepting the lowest tender, to cheap and untrained physicians. The consequence might have been foreseen; such concerns are "not at all enthusiastic over the results of industrial medicine and surgery."

Thus, while industrial medicine and surgery have "arrived," there still remains to be done a great deal of spade work. There are many industrial establishments in which these methods are yet unknown or inadequately applied. There are others where a totally erroneous conception of the scope and function of the medical services has prevailed.

Dr. Mock's book is, therefore, in some sense a pioneer work. Not only has he to propound to the convinced industrial physician a sound doctrine of practice, but he must instruct the neophyte in fundamental principles, and also provide the propagandist with arguments wherewith to "sell" the heads of industry on the idea.

While the necessity for these varied functions makes the work more interesting to the non-specialist, it renders it probable that subsequent editors will separate the propaganda from the systematic part; or, which is even more probable, "Mock" will become the classic on industrial

* Industrial Medicine and Surgery. By Harry E. Mock, B.S., M.D., F.A.C.S.; assistant professor of industrial medicine at Rush Medical College; chief surgeon to Sears, Roebuck Company; Lieutenant Colonel, M.C., United States Army. Cloth, 8vo, pp. 846, illustrated, $10. W. B. Saunders Company, Philadelphia, 1919.

medicine and surgery, an eminence amply justified by the author's personal efforts in that field and the merits of the book itself.

So far as the general part of the work is concerned, its doctrine may be summed up in the proposition that the medical department of an industrial concern should properly be the "Human Maintenance Service."

The book is divided into six parts: (1) Industrial Health Service; (2) Prevention; (3) Industrial Medicine; (4) Industrial Surgery; (5) Compensation Insurance, medico-legal phases; and (6) Reconstruction.

The plan which has determined the distribution of the subject matter among these divisions is not always clear. This is especially the case in the first two, in which there is considerable overlapping and repetition. In reading the book one receives a recurrent impression of a series of detached articles, independently written, with much common subject matter, and subsequently brought into outward unity to make a book. This may be the true genesis of the work. On the other hand, the repetition and overlapping may have been intentional, and designed to give as much completeness as possible to each section.

Under the heading of industrial health service are treated the personnel and the equipment of the medical department and the scope of its activities. The construction of the office and dispensary is discussed with sufficient detail. On the question of whole-time or part-time physicians Dr. Mock is clearly in favor of the latter, though in some passages he appears to make it merely a question of the ability of a concern to provide an adequate salary for a whole-time man of the required caliber. A book such as that now under review is a work of years, and it may be that the uncertain sound of such passages is a reflex of the author's varying state of mind. At present he has settled to the following position: "While many expert company surgeons devote all of their time to the industries employing them, yet, as a rule, better trained and more able physicians can be secured if employers require them to give only part of their time to this work." (p. 43.)

Dr. Mock points out as an advantage of the part-time system the employment of two or of several men who, being well grounded in the general work, can relieve each other for such purposes and yet may, as specialists in different branches, each use his special knowledge as occasion may arise. Of such an arrangement he says: "The remainder of the day they have free to themselves to develop their special line of work and, incidentally, they are becoming more valuable to the concern because of this development. The salaries paid these men are good, but the concern could not employ them for full time without an outlay that would make it prohibitive. But . . . their combined salaries do not exceed what the concern would pay for one mediocre physician giving his full time to the work."

On the nurse in industry a special chapter is contributed by Miss Mae Middleton. More than two-thirds of her report is taken up with illustrative cases, largely of an anecdotal type. The collation of the meager information it affords with that found in other parts of the book brings home forcibly the fact that the nurse is the pivot of the system.

Dr. Mock is for the most extended application of human maintenance and, therefore, is an advocate of what is ordinarily called social welfare work being done in the families of employees at the cost of the employer, and this not merely on humanitarian, but also on economic, not to say selfish, grounds.

On the same principle, our author is strongly in favor of placing the medical services and the mechanical safety services under one head, so that their activities may be only coördinated.

The cost of good human maintenance service, exclusive of home treatment and the medical care of employees' families, appears to be about $2.25 *per caput, per annum.*

Four concerns which give, in addition, sickness treatment to employees and their families in their homes, pay $6.46 (chemical works), $3.89 (textile), $14.24 (gold mining), and $11.82 (coal and iron mining), for the complete service.

Even these seemingly high annual charges represent increases of the daily wage by a fraction more than one cent in the lowest and about four cents in the highest case. In these days such figures are negligible.

The question of physical examination of applicant for employment is notoriously a ticklish one. In connection with it the interests of industrial hygiene and medicine are likely to clash with the prejudices of organized labor. The present work deals very fully and very fairly with this question, although the information relating to the subject is somewhat scattered. Dr. Mock believes that experience of the benefits and tactful explanations will remove obstacles due to suspicion that the examination is intended as a cloak to hide the machinations of the opponents of organized labor.

The percentage of absolute rejections is small. The most important functions of the examination are the fitting of men to jobs, the prevention of accidents due to partial incapacity, and the opening of a medical record for the employee.

A chapter on women in industry draws largely on war experience and deals helpfully and in detail with such matters as the technic of routine physical examination and the provision of facilities for resting.

The problem of the tuberculous employee is treated from the hygienic, statistical, sanitary, and rehabilitation points of view.

It is evident that the medical treatment of employees is far less special than is the surgical work. Consequently, comparatively little space is devoted to it. While the highest grade of surgical skill and knowledge are presumed in the industrial surgeon, the excellent and highly practical chapters in industrial surgery will be of inestimable value to him. They are packed as full of practical information as an egg is of meat.

A commendable feature is the "plumping" for what has proved, in the author's own experience, the best method in each case. The attitude that Dr. Mock seems to take is this: "While such-and-such a method is recommended by So-and-So, and this other by Such-an-One, and while no doubt each has merits and special advantages in particular cases, I have found the method here described gives full satisfaction in the general case." One cannot better 100 per cent.

In this way, for instance, Dr. Mock comes out strong for the immediate and free use of tincture of iodin. He points out that one of the most fruitful causes of sickness, of loss of time, and often of compensable injury, is the neglect of slight traumata, resulting in serious infection. He considers that emphasis on the need for immediate treatment of the slightest trauma by tincture of iodin and suitable protection, is one of the most important points of industrial surgery.

Orthopedics, especially reëducation, receives full attention. There is a special detached chapter on human conservation and reclamation of the disabled.

The closing sections are concerned with employees' compensation from the medical viewpoint, and similar subjects, with a strong argument in favor of health insurance and for the Americanization of the foreign employee.

Dr. Mock has produced a work of which American medicine has just reason to be proud. It is not merely a monument of hygienic, social, and medical progress; it is also an invaluable and what will become an indispensable handbook to those engaged in industrial medicine and surgery.

SAFETY COUNCIL COMMITTEE STUDIES DERMATOSES

Skin diseases or dermatoses are prevalent among workers in certain industries, and in some cases are caused by or aggravated by the conditions to which the worker is exposed, but there is very little accurate information as to their cause and methods of prevention. This led the Health Service Section of the National Safety Council, at the recent Congress, to form a special committee to investigate and report on this subject. This Committee consists of three men of the highest standing in the medical and industrial world—Dr. Carey P. McCord, director, department industrial medicine and public health, University of Cincinnati; Dr. C. A. Lauer, medical director, Westinghouse Electric & Manufacturing Co.; Dr. C. F. N. Schram, medical director, Fairbanks, Morse & Co.

In the questionnaire sent out to the members of the National Safety Council, the Committee offers to serve as a clearing house for the collection and dissemination of data on the best modes of preventing and controlling skin diseases, and the best methods of treatment.

The list, confessedly incomplete, it is hoped will be rounded out from the data obtained through the following questionnaire:

1. Do you wish the information supplied below regarded as confidential?
2. Name and address of the plant
3. Name and title of the person supplying this information
4. Number of employees Male Female
5. General nature of the product of the plant
6. What particular processes are involved in the manufacturing of the products of your plant?
7. Do you know of the existence at the present time, or at any time in the past, of any kind of skin disease among the workers in any part of the plant?
8. Please supply all possible information as to the nature and characteristics of the skin disease observed
9. Have you on hand, or can you obtain, "close-up" photographs of these skin diseases? (Please include photograph when returning this questionnaire.)
10. In what particular manufacturing process did such conditions arise? Please supply full details.
11. What percentage of persons in any involved department were affected? Total number affected.
12. What has been the method of caring for and treating such patients?
13. What measures have been installed for the elimination of these conditions?
14. Are the protective measures instituted adequate?
15. In other plants in which you may have connections, or with which you may be familiar, do you know of the occurrence of any skin disease attributable to working conditions or to trade processes? If so, please supply all possible information.
16. What general and specific processes do you believe this Committee should investigate as probable prolific sources of dermatoses? This question does not apply to your own plant, but to industry in general.
17. Please refer us to any papers you may have published on industrial skin diseases or to any other published work of this nature with which you may be acquainted.
18. Please write your own views with reference to industrial dermatoses,—prevalence, frequency, causes, methods of treatment, and their significance as an industrial medical problem.

Information is asked concerning the following list of industries and trade processes in which cases of industrial skin diseases are known to have developed.

Industry	*Trade Processes*
Anilin dyes	
Automobiles and parts	Machine shopping (oil)
Bakelite	
Boots and shoes	Closing and blackening
Boxes, fancy and paper	Paper box making (glue)
Brass and bronze products	Acid dipping
Clothing and textiles	Cleaning, dyeing
Cordage, twine, jute	Combing, stranding (oil)
Dry cleaning and dyeing	Dyeing and cleaning
Electrical apparatus, etc	Pitching dry batteries
Enameling and japanning	Enameling
Foundry and machine shop products	Welding, electroplating
Furniture and cabinets	Polishing and veneering
Glass manufacturing	Mixing ingredients (arsenic); decorating (benzin)
Halowax	
Iron and steel mills	Galvanizing (sal ammoniac)
Lime manufacturing	Grinding, slaking
Marble and stone	Surfacing (oxalic acid)
Oil cloth and linoleum	Mixing ingredients
Paint and varnish manufacturing	Cleaning with benzine, mfg. varnish
Paper and Roofing paper	Sizing with alum
Rubber goods	Specialty work, making inner tubes, cold cure
Soap	Handling soap
Stereo- and electrotyping	Tending batteries
Stoves and furnaces	Metal cleaning (naphtha)
Toys and games	Brazing

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

THE ROLE OF DIETETICS IN THE PUBLIC HEALTH CAMPAIGN

THE sanitation of food supplies has long received its full share of the attention of public authorities. Indeed, the natural fear of adulterated food and the ease with which this fear can be played upon by the intellectually unscrupulous demagogue have at times caused an altogether excessive emphasis to be laid upon this problem.

It is impossible to stress too strongly the need for the filtration or disinfection of water supplies and the pasteurization of milk, since experience has demonstrated, again and again, that untreated surface water and raw milk are always and everywhere likely to be the bearers of the germs of communicable disease. Shellfish layings should be supervised, slaughter houses controlled, food stores inspected, and food handlers examined, as part of the routine of an adequate department of health. Furthermore, in the interest of honesty if not of hygiene, the laws against adulteration and misbranding should be vigorously enforced; and care should be taken to preserve foods with care and to avoid those foods which are under suspicion of being decomposed.

From the standpoint of the health officer interested in the saving of a maximum number of lives, there is, however, another aspect of the food problem that is more important than all the rest put together. The number of individuals suffering from an insufficient dietary is vastly greater than the number of those made ill by all kinds of positively deleterious conditions of the food supply. We may maintain a certain skepticism in regard to the estimate that 20 per cent of the school children of America are under-nourished; but malnutrition is a very real and a very serious burden upon our national vitality, and a burden which appears to have grown heavier during the past five years. Food hygiene, the science of the selection of an adequate diet, is even more important in the long run than food sanitation. The unintelligent housewife is our problem, rather than the wicked grocer; and, as in so many other fields of public health, this problem can be solved only by education.

It is a sign of the times that Overton and Denno's admirable book on The Health Officer[1] devotes thirteen pages to food sanitation and fifteen to food values. It is significant that the more progressive visiting nurse associations are employing dietitians and visiting housekeepers as regular members of their staffs, and that municipal and state departments of health devote increasing space in their bulletins to the problem of food costs. In the schools the Child Health Organization is making a vigorous campaign for "a scale in every school" and for the use of the increase in a child's weight as a simple index of development and an opening wedge for education in food hygiene.

The work of Sherman and Lusk, of Mendel and McCollum, has laid a sound basis for the dietary teaching which should be an essential part of the work, not only of every health official, but of every practising physician as well. These investigators have made it clear that in order to obtain a diet adequate in calories, in amount and kind of protein, in salts and vitamines, at a mimimum cost, it is essential that the average food habits of the American household should be materially modified. Grain products must, of course, form the staple of the calorie allowance; but they should be supplemented far less by meat, fish, and eggs, far more by milk, vegetables, and fruits than is ordinarily the case. A reduction in meat consumption, an increase in the use of fruits and green vegetables, and particularly an increase in the consumption of milk,—these are the primary elements in the campaign for dietary hygiene. Doctor Lusk has formulated the rule that "you should never buy a pound of meat until

1. The Health Officer. By Frank Overton, M.D., and Willard J. Denno, M.D. W. B. Saunders Company, Philadelphia, 1919.

you have bought three quarts of milk," and the Department of Public Health of the American Museum of Natural History has prepared a model dietary for a family of five, which assigns the weekly food budget in the accompanying table.

The imperative necessity of knowing something about food requirements and food values must be brought home to the people and the dissemination of dietary standards of this kind will be likely to accomplish more in the actual promotion of physical health than any possible exercise of police power along the traditional lines of food sanitation. EDITOR.

BUDGET FOR A FAMILY OF FIVE FOR A WEEK

Type of Food	Amount	Per cent of Total Food Budget
Milk	21 qts.	26
Grain products	20 lbs.	15
Vegetables	23 lbs.	14
Fruit	8¾ lbs.	12
Meat and fish	6¼ lbs.	11
Fats	3½ lbs.	10
Cheese	1 lb.	3
Sugar	4 lbs.	3
Eggs	½ doz.	2
Nut products	½ lb.	1
Coffee	¼ lb.	1

Total cost, August, 1919, $12.

PRACTICAL APPLICATION OF IMMUNITY IN TUBERCULOSIS

BY W. H. WATTERSON, SURGEON, UNITED STATES PUBLIC HEALTH SERVICE (R.); TUBERCULOSIS EXPERT FOR THE FEDERAL BOARD FOR VOCATIONAL EDUCATION, WASHINGTON, D. C.

IMMUNITY is defined by Col. George E. Bushnell as resistance to an infection so severe that it would unfavorably affect or kill organisms that have not been thus infected and thereby immuninized,—a relative exemption from disease. This immunity may be divided as racial, acquired, or inherited.

Racial Immunity

Racial immunity to tuberculosis is well established,—the Hebrew having acquired immunity through centuries, as noted by the archives of history of tuberculosis among them. Today those of this race having tuberculosis are at once given a better prognosis than those of any other race.

The Irish and Swede on the other hand have had little history of this disease among them until recent centuries, and lack the racial immunity of the Hebrew, and among them the prognosis is not good and mortality is high.

The Negro, brought into slavery from a tuberculosis free nation, less than four hundred years ago, shows a death rate of three to one compared with the white man, and that this is not all racial is evidenced by the lessening proportionate death rate, as generations acquire added immunity to the disease.

The Indian, the true American, wandered about our land without tuberculosis until forced to come in contact with the tuberculous white. Opportunity for acquiring immunity had been present neither in childhood or in previous generations, and, like the prairie fire, it swept through their tribes, taking five Indians to one white man and leaving but a vestige of the once bold huntsmen of the plains. That this was not all due to racial immunity is evidenced by the fact that one tribe in Mexico, found to have had tuberculosis for many generations, shows an immunity similar to that of the white.

The Esquimos, the most recent example of lack of racial immunity, plied their trade through Canada and the occasional ships that touched their shores, free from tuberculosis, until the gold rush to Alaska took the infected among them. This virgin soil responded quickly, and a death rate of ten to one white is reported. Can we explain this otherwise than on that of racial immunity?

Acquired Immunity

Acquired immunity was evidenced in a study of our army and many other studies of the day. Little primary tuberculosis was found among our troops, though opportunity for infection was very great. A new disease to which they were not immune came among them, and influenza was rife. Acquired immunity is the greatest hope of today in the treatment of tuberculosis.

"The opportunity of infection," as Colonel Bushnell puts it, "had come to most of our boys and the resulting immunity prevented an epidemic of tuberculosis, like that of influenza."

Here comes the meat of today's opportunity to the tuberculosis worker. Infection by the tubercle bacilli is almost universal in civilized tribes by the time the age of twelve is attained; let us make use of this opportunity for immunity by the careful guidance of the infected, that their infection, in the first place, be not massive to their organism, and, second, that the organism may be supported during the building of immunity.

The child under two years of age is especially subject to gross infection and must be kept from the massive infection of the tuberculous parent, maid, or nurse. As years go on infection is sure to come, though seldom in massive doses, and with it immunity is acquired; without this early infection non-immunity leaves a fertile soil for infection at some future date.

Principles of Acquired Immunity

The Turkish medical student exemplifies the principles of acquired immunity. The students from the hills and agricultural districts showed little immunity to the disease; while those of the city showed a high degree of resistance; this resulted in much primary infection among the students from the rural districts and little among those of the urban class. Romer draws the conclusion from this observation:

"The less extensive the prevalence of tuberculosis in a population, the greater the fatality of tuberculosis; or, reversing the proposition, the more widespread tuberculosis infection is in a population, the less fatal the form of the disease."

The Question of Inherited Immunity

Inherited immunity is not so well established and yet it furnishes the foundation for racial immunity. Certainly the degree of inherited immunity is not as great as that of racial immunity, but nevertheless it is present, and we may safely say that the child of the tuberculous mother, properly cared for after its birth, is less prone to disturbance from tuberculous infection than the child of the healthy mother. The only absolute proof an animal is *not* tuberculous is to grind up and inject a guinea pig with every part of animal.

Primary infection occurs very early. Hardly a child reaches the age of two without showing positive reaction to tuberculosis, *i.e.*, evidence that he has been infected. That every infected child does not die is due to the fact that the infection at no time has been "massive" to that child and, therefore, stimulated further immunity, rather than overwhelmed the resistance of the individual.

Four Classes of the Tuberculous

Class 1.—The individual infected belonging to this class is able to withstand his infection, without any unfavorable effect.

Class 2.—To this class belongs the individual whose infection affects him to the unfavorable extent that he knows there is something wrong; but a sea-voyage vacation, or a change in his mode of life or occupation, restores him without examination by his physician or, if examined, tuberculosis is not diagnosed. The mother notices that her child's appetite is not good; he is reluctant to join his playmates at the most enticing amusements; he sleeps poorly; enlarged tonsils, adenoids, and cervical glands may be noted. Yet the child is never thought to be tuberculous, and a summer's vacation or a month at a resort or on the farm changes that unbalanced immunity, and autumn finds the child in the rose of health. Immunity to tuberculosis has been greatly increased by this experience, which at most would elicit diagnosis of scrofula, or "Tonsillitis," "Adenoids," "Indigestion," etc.

Class 3.—The infection in Class 3 so unfavorably affects the patient as to produce marked symptoms. There are noted, in the child, retardation of growth and development; in adults, afternoon temperature, rise in pulse, digestive disturbances, cough, and sweats. Physical examination reveals changes in the lung; in the primary infection these changes are râles only; in the exacerbation cases, there exists evidence of old lesions upon which is superimposed the evidence of an extension of the disease. A diagnosis of tuberculosis is usually made, and sanatorium treatment either in sanatorium or at home is insisted upon. Some *sanatorium treatment is essential to raise the immunity to the point of balance.* More or less destruction of tissue is sure to result before this balance is attained. The resistance is again raised and resistance is established to the point of ever increasing the immunity. The steps of recovery, improvement, quiescence, and apparent arrest, depend on the relative symptoms more than the signs, and on the time last symptoms or signs were noted.

Class 4.—Here the infection has produced all the unfavorable effects noted in Class 3. The individual may take advantage of every means to again restore his immunity or he may not resort to such restorative measures; in either case the ability to restore immunity is not sufficient. The resulting increased toxins destroy tissues and lessen the amount of functionating lung; other organs become involved or general toxemia brings a speedy end. We have here the picture of what is called "quick or galloping consumption."

Progress by Insensible Degrees

How are we to judge to what class a given patient belongs? No one, by any scientific means now at hand, can judge to which class the patient belongs after passing Class 1; therefore, every tuberculous patient should avail himself of the tripod in treatment,—rest, diet, and fresh air.

It is known that the glands and blood have a relatively easy chance to increase the immunity

in youth; but that when primary infection occurs in adults, this power is not very active, which explains the result in Turkish students. Individuals not now infected will be, under present conditions in all civilized countries, and the chances are rather high for adult infections to progress to Class 4. Thus, it may be said that infection in childhood is a fortunate asset, to the child, against future infection. The guinea pig, a most susceptible animal, infected by large doses of tubercle bacilli, quickly dies of generalized tuberculosis; but, if infected by a small dose of tubercle bacilli, recovers after having developed temperature and other evidence of toxemia. A few months later this same guinea pig, injected by a much larger dose of tubercle bacilli, showed a different response to infection. There usually follows a local reaction, possibly a local abscess; but there is no general reaction; no temperature; that is, an immunity has been established as a result of the first infection. This immunity is common with all. Immunity is *partial*, there being no such thing as a perfect immunity. Therefore, a large enough dose may be given this pig on the second or third injection to be a "massive" infection, and an overwhelming toxemia will result. The chances of such occurrence lessen with each gradually larger dose of infection, until any ordinary amount of infection has no ill effect. Immune persons are in the position of the guinea pig, having received increasing injections until immunity approaches perfection. The results and practical applications of the principles are: Practically all tuberculosis in the army is an exacerbation of an old infection in an immunized individual. This immunity has been lowered by some such unusual strain as trench hardships, and this temporary deficit in immunity is usually so slight that it may be overcome by such trifling helps as rest, diet, and fresh air.

The Means of Infection

It follows that the danger in the tuberculosis hospital has been exaggerated; three nurses die of tuberculosis in a general hospital to one in a tuberculosis hospital. It is exceedingly rare that orderlies, maids, and attendants in a tuberculosis hospital have tuberculosis, notwithstanding that some 90 per cent of the physicians employed in tuberculosis hospitals before the war had been attracted to that specialty either because of previous tuberculous disease in themselves or in some member of their family; yet proportionately more physicians in general practice die of tuberculosis than of those employed in tuberculosis sanatoriums. The real danger from tuberculosis is not by breathing the air in a tuberculosis ward, but from *contact* with the case. Such simple rules as, "Wash your hands after your duties and don't eat in the ward," obviate most of the danger of the massive infection. The greatest danger lies in the massive infection of the child by a tuberculous parent who fondles her child, or is so careless with sputa that the child creeps into the sputa-smeared floor, and then conveys this massive infection to the mouth from his hands.

The object of this paper would have been defeated, if in the least it minimized the importance of the care of sputa. Little is known of what constitutes the massive dose for any one; and, aside from personal danger, our duty must extend to the patient himself, who, already having lowered his immunity, must not be permitted to add to the burden of restoration. Most of all, we must ever make the patient careful for the sake of that non-immune babe at home to whom he is to go, to whom he will most certainly carry the infection in massive doses unless we perform our duty of constantly warning the patient properly to dispose of his sputa. He, of all others, is unable to measure the dose or virulence of his infection.

THE TEACHING OF PRACTICAL MIDWIFERY

The appalling death rate, almost entirely preventable, from childbirth in England will never be reduced to a minimum until the hospitalization for lying-in cases is greatly increased, says *The Lancet* of December 13, 1919, in reporting the discussion of the Obstetrical Section of the Royal Society of Medicine; nor will facilities for the proper training of the medical student and the midwife in obstetrics be adequate until the hospital beds available for teaching purposes are far in excess of the present proportion.

The policy regarding hospital accommodation contemplated by the Ministry of Health will involve complete reorganization of the Poor-Law infirmaries and a reconsideration of their relationship to general hospitals and to the hospitals associated with medical schools; and in connection with this latter relationship some means should be found for making use of the vast amount of material in these institutions for clinical teaching. The teachers in midwifery at the medical schools should remember that if the suffering and mortality of childbirth are to be ameliorated, any plans must improve the teaching not only of the medical student but also of the midwife.

Accommodations temporarily provided for maternity cases in the smaller hospitals are admittedly defective, and these should ultimately be affiliated to the larger institutions so that they may be able to command the services of experts who form members of these staffs. The provision of large maternity centers in various parts of London, fully equipped for the reception of lying-in cases and perhaps also for gynecological cases, and certainly should be associated with maternity and child welfare centers, must be a feature of hospital evolution.

The Obstetrical Section is urged to draw up alternate schemes so that in the development of the plans of the Ministry of Health the teaching of midwifery will be provided for under a well defined policy.

A COATING FOR POISON TABLETS FOR THE PREVENTION OF ACCIDENTAL POISONING

By GRAY PHILLIPS, M.D., Brooklyn, N. Y.

MORTALITY statistics show that a considerable number of deaths are caused every year by the accidental swallowing of mercuric chlorid and other poison tablets. Although complete figures are not available, the mortality experience of the Metropolitan Life Insurance Company in their industrial department may be taken as representing the extent of such poisonings among the entire population of the country.

Deaths Charged to Accident

During the single year of 1917, in which such a separate tabulation was made, 180 deaths were charged to accidental poisoning by solid or liquid poisons, and of these, 26, or 14.4 per cent, were reported as due to bichlorid of mercury. It should be remembered, however, that although these deaths are reported as accidental they undoubtedly include poisonings involving suicidal intent. Even making allowance for such exceptions it is evident that a considerable number of deaths occur each year which are due to the accidental swallowing of bichlorid of mercury tablets. The growing domestic use of germicidal tablets is responsible for the increasing frequency of these accidents, while the publicity given poisoning cases by the press undoubtedly suggests the use of bichlorid to those unfortunates who seek some convenient and sure means of self-destruction.

The majority of these poisonings are preventable but their prevention rests upon some means more sure than any or all of the safeguards yet devised. With this purpose in mind, the author has developed a coating intended to render poison tablets innocuous when swallowed, but which interferes in no way with their use for making germicidal solutions.

Poison Rendered Innocuous

The contrivance consists of a coating of wax, the wax having a melting point above the highest climatic temperature, one which is not brittle and therefore which will not crack or scale from the tablet in handling; and, above all, which not only is insoluble in water but is not affected by the digestive juices. Tablets coated with such a wax pass through the alimentary tract unchanged and consequently prevent any solution or absorption of the tablet substance while in the body. By breaking the tablets they may be readily dissolved when it is desired to prepare solutions from them.

After many trials, during which a large variety of substances has been rejected as unsuitable for this purpose, a coating has been developed which not only satisfies all theoretical requirements but which meets every demand for practicability. By mixing equal parts by weight of candelilla wax and a paraffin having a melting point of 56°C., a wax is obtained which melts at 70°C., which has a low coefficient of expansion and, therefore, little brittleness; which is unaffected by dilute acids and alkalies and which is not attacked by digestive ferments. Furthermore, the device represents no serious difficulties as to manufacture. The machines employed for coating pills with gelatin are equally well adapted for applying the wax coating to tablets, while the combined cost of the materials and the process for quantity production is negligible.

The perfected coating has the added advantages of protecting the tablet from moisture, and from breaking or crumbling in the container. Deterioration is prevented, and exact dosage is assured.

A Test of Its Efficacy

In order to put the efficacy of this wax coating to a practical test the following experiments were carried out:

Experiment I.—As a preliminary control, three individuals swallowed one, two, and three uncoated one-grain tablets of methylene blue, respectively. The dye appeared in the urine of all three and in the case of the individual taking three tablets it persisted for forty-eight hours. When the urine no longer showed any trace of the dye the same individuals swallowed one, two, and three one-grain methylene blue tablets covered with the protective wax coating. This test was then repeated several times with ten individuals, the coated tablets being taken on an empty stomach and just prior to and after a hearty meal. In no case did any dye appear in the urine, and the tablets were recovered from the feces with the coating intact.

Experiment II.—A normal dog, fed on a full diet of meat, bread, milk, and water, was given three one-grain methylene blue pills provided with the wax coating. During the whole period of observation no dye was excreted in the urine and fifty hours after ingestion of the tablets they were recovered intact from the feces.

These experiments show that the wax coating is neither dissolved nor digested in the alimentary tract of man and resists the greater gastric acidity and longer sojourn in the intestine of the dog. Further, no diffusion of the ingredients of the tablet takes place through the coating. The wax envelope, therefore, resists the digestive fluids, is impervious to diffusion of

crystalloids, and, while having a melting point high enough to remain unaffected at temperatures far above those of the body, the coating would be sufficiently flexible to retain perfect cohesion when subjected to the tumbling it suffers in the digestive canal.

As additional safeguards it might be desirable to impart to the wax coating a distinctive color; to incorporate in it some gritty substance, such as sand, which would warn the person biting or chewing the tablet that it was inedible, and also to add to the coating some bitter principle.

A wax coating has been devised which can be easily applied to poison tablets and which is intended to lessen the possibility of accidental poisoning. This coating, being insoluble and indigestible in the digestive tract, prevents the solution of the tablets while in the body; but in no way interferes with their use in making germicidal solutions.

A CRITICAL SURVEY OF PUBLIC HEALTH TOPICS

By JULES SCHEVITZ, General Secretary, Oklahoma Tuberculosis Association, Oklahoma City, Okla.

I. Automobile Fatalities in the United States.
II. Infant Mortality in Saginaw, Mich.
III. Bad Housing and Ill Health.

I—AUTOMOBILE FATALITIES IN THE UNITED STATES

SOME very convincing and startling evidence that automobile fatalities are assuming large proportions in this country each year appears in a recent issue of the *Monthly Bulletin*[1] of the Newark, N.J., Department of Health. Statistics of fatalities for twelve large American cities are given for the years 1909 to 1918, and it is observed that while the average rate for the first half of the decade was 33.8 per million population, the rate for the second half, 1914-1918, increased to 99.4 per million.

On page 157 is presented a table taken from the article giving the mortality from automobile accidents in the United States registration area for 1906-1917 which shows conclusively that the automobile has become a serious menace.

In 1906 there were only 183 fatalities from automobile accidents in the registration area, but by 1917 this number had increased to 624. In the urban area the rate increased from 6.3 per million population in 1906 to 95.1 in 1916, while in the rural area the rate increased from 1.3 to 48.5 during the same period. Says the author of the article, "These figures are startling but true, and are a clear indication of the future, unless more intelligent, extensive, and vigorous organized effort is made to abate what has become not much less than a crime against our boasted civilization."

1. Monthly Bulletin, 1919, n. s., iii, No. 33.

That education and regulation will help reduce these fatalities is borne out in numerous instances where intensive effort has brought about a decided decrease in automobile fatality. In New York City, with the most carefully policed traffic in the United States, the rate of automobile fatalities has been the lowest.

The sex distribution of the automobile fatalities is an interesting feature of the problem. It is found that there are about four fatalities among males to every one among females. The age distribution reveals that about one-half the fatalities occur between the ages of twenty and fifty-nine years and about 40 per cent under twenty years.

II. INFANT MORTALITY IN SAGINAW, MICHIGAN

THE social and economic conditions underlying infant mortality have been the subject of intensive inquiry by investigators working under municipal, state, and national direction. Perhaps the most noteworthy and exhaustive of these are the brilliant researches conducted under the auspices of the Children's Bureau which has in the last few years reported on a series of studies on the causes of infant mortality in Johnstown, Pa., Manchester, N. H., Brockton, Mass., and Saginaw, Mich. The results of these studies possess the added value of offering a basis for comparison in that in the last three cities named the methods of procedure were practically identical.

The study of infant mortality in Saginaw,

Mich., is of special significance because of the city's unlikeness to those previously visited. Saginaw is a city of widely diversified industrial life, located in a rich agricultural region. It possesses, therefore, few of the characteristics of Johnstown, Manchester, and Brockton which are, respectively, iron and steel, textile mill, and shoe factory cities. Furthermore, Saginaw had the relatively small foreign born population of only 23.2 per cent; and comparatively few women were employed in industry, as compared with the large proportion at work in the textile mills of Manchester.

Included in the study are 1,015 births occurring during the year ending November 30, 1913, and the deaths under one year of age occurring in this group. Thirty-four, or 3.3 per cent were stillbirths, and 83 of the 981 live-born infants died, giving a mortality rate of 84.6 per 1,000.

The father's earnings are assumed to be the best obtainable index of the economic status and the standard of living of the family. A striking relationship between the infant mortality and the father's earnings is shown in the following figures:

Earnings of Father	Infant Mortality Rate per M.
Under $450	179.5
$ 450 to $ 549	112.2
$ 550 to $ 649	103.4
$ 650 to $ 849	105.7
$ 850 to $1,049	44.6
$1,050 to $1,249	33.0
$1,250 and over	22.2
Average	84.6

Analysis of these data brings out the significance of the standard of living of the family in its necessarily important bearing upon the vitality of the children.

The mortality rate with but a single exception falls consistently as the father's earnings increase, but the rate does not fall below one hundred until the group of $850 to $1,049 is reached. In other words, the babies in families where the earnings of the families are low die at a much higher rate than do those whose fathers are able to provide sufficient care for them.

The infant mortality rate in the lowest and highest earnings groups were 201.9 and 59.9 for New Bedford and 242.9 and 58.3 for Manchester, respectively. The higher economic status of the Saginaw families is described in the following paragraph quoted from the Children's Bureau report.

> Saginaw is in the center of a rich farming country and prices of food products are relatively low, with no commission, storage, or transportation charges to be paid. Beet sugar is made in a factory just outside the city limits. Rents are low. Nearly one-half of the families visited owned their own homes. In many cases the home is set in a small plot of ground, with a few fruit trees, a wired inclosure for chickens, and a thriftily cultivated vegetable garden. The cost of fuel is low, partly on account of the presence of coal mines in the city, some of which are cooperatively owned. With these advantages, the small family of Saginaw can live in simple comfort on earnings that would spell poverty for the tenement-housed families in other or larger cities.

Further emphasis of the relatively high economic status of the Saginaw group can be seen from the following figures showing the percentage distribution of births in the three cities according to father's earnings groups.

	Under $550	$550-$849	$850 and over
Saginaw	17.9%	40.0%	39.0%
Manchester	30.4%	44.0%	22.9%
New Bedford	37.7%	38.0%	21.3%

The gainful employment of the mother during the year preceding the birth of the infant appears to be a factor in the causation of a high infant mortality. The mortality rate for the infants of working mothers was 132.7, as contrasted with 78.3 for infants of mothers not gainfully employed. Figures collected in other cities show a difference in the infant mortality when the mother is employed away from home in distinction from being employed at home, the rate being lower in the latter group. Another interesting observation is that although only one-fifth

AUTOMOBILE FATALITIES IN 1906-1917 IN THE UNITED STATES REGISTRATION AREA

	Total Area (Registration) Fatalities		Urban Area Fatalities		Rural Area Fatalities	
Year	No.	Rate	No.	Rate	No.	Rate
1906	183	4.4	163	6.3	20	1.3
1907	294	6.8	240	9.1	54	3.5
1908	393	8.4	322	11.7	71	4.1
1909	632	12.4	500	16.9	132	6.2
1910	980	18.2	721	23.1	259	11.5
1911	1,291	21.8	985	30.4	306	11.4
1912	1,758	29.1	1,316	39.5	442	16.3
1913	2,488	39.3	1,801	52.6	687	23.6
1914	2,826	42.8	1,930	54.9	896	29.1
1915	3,978	59.1	2,752	75.9	1,226	39.5
1916	5,193	72.5	3,509	95.1	1,684	48.5
1917	6,724	88.6	Data not yet available			
1906-09	1,502	8.2	1,225		277	
1910-13	6,517	27.5	4,823		1,694	
1914-17	18,721	66.7				
1914-16			8,191		3,806	

of the foreign born mothers were employed, one-third of the infant deaths in this nativity group occurred among their babies.

The employment of the mother during the year following the birth of the infant does not seem to have had an unfavorable effect on the infant mortality, according to the data gathered at Saginaw. This may possibly be due to the fact that only few mothers were thus gainfully employed.

Certain workers, notably Dr. Julius Levy, of Newark, regard the employment of the mother at this time of even greater importance than the father's earnings in determining infant mortality. It is claimed that the detrimental effect of the mother's employment lies primarily in her inability to give her child sufficient maternal care. In order to reduce infant mortality we must guarantee "to every baby its birthright of maternal nursing and 'mothering,' and to every mother her maternal right and privilege to mother and nurse her own infant," states Doctor Levy.[2]

Of the infants surviving at the end of the first month, 87.9 per cent were exclusively breast fed. The large proportion of breast fed infants gives very little chance for gasto-intestinal diseases; only a very small percentage of deaths resulted from that cause. Thus one of the most important factors in the causation of infant deaths was reduced to a large extent. The mortality among artificially fed infants was much greater; throughout the first nine months the rate was at least twice as high.

Of 117 losses studied, thirty-four were still-births, and thirty-four were deaths under two weeks of age. Eighteen of the deaths at later ages were due to causes peculiar to early infancy and malformations, making prenatal causes responsible for more than two-thirds of the total losses. According to the leading authorities, these losses can be reduced by care of the mother during pregnancy and by good obstetrics.

III—BAD HOUSING AND ILL HEALTH

That bad housing is frequently a contributory factor in the causation of disease,—especially communicable disease,—is generally accepted by health workers but, unfortunately, very little has been done to ascertain in a scientific manner those conditions which have this detrimental effect. Some of the undesirable features in house construction are given by Prof. James Ford,[3] and many of these are especially inherent in the multiple type of dwelling.

This type of dwelling is described by Professor Ford as "a structure five or six stories high, or perhaps higher, built largely of wood, but with brick exterior, three or four rooms deep, sharing party walls with similar buildings to the right and left, sharing with its neighbors a narrow court or shaft, at the sides and at the rear an ugly yard, with board fences, filled with clothes lines and drying clothes, outbuildings, and probably ash, garbage, and refuse cans; and in the front sharing with its neighbors an ugly, monotonous, treeless, dusty, paved street."

This picture describes the urban home of the middle classes, but in describing the homes of the wage earners who constitute the major part of our urban population, must be added the inevitable dark hallway, the common toilet, disrepair, and unsanitary conditions resulting from years of careless usage.

Such dwellings may contribute to ill health on the part of the occupants through the following conditions:

1. Through improper location, by building on wet and imperfectly drained land, or by placing the building in a highly exposed position.
2. Through use of wood for interior or exterior construction, tenants are exposed to continuous fire risk.
3. Through defective structure or bad repair, there may be continuous danger to life and limb from accident.
4. Through defective orientation, tenants may be deprived of sunshine, and even of adequate light.
5. Through excessive height, there is not only an increased fire risk, but stair-climbing is a hardship to the aged, and a limitation to the play activities of the young.
6. Through crowding of many families in the same building, the chances of exposure to certain infectious diseases are increased.
7. Through crowding of population within the tenement, block, or district, the density of population adds to the nervous wear and tear and sleeplessness.
8. Through crowding of rooms, the chances of communicating disease by direct contact or droplet infection are increased.
9. Through inadequate plumbing, such as lack of water supply, personal cleanliness and housecleaning become more difficult.
10. Through poor ventilation, due to windowless rooms or other reasons, there are discomfort and possibly reduced resistance to disease.
11. Through poor lighting, the rooms which are dark are likely to be dirty. It may also result in impairment of vision.
12. Through improper equipment, such as a sink set too low, a leaky stove, defective gas fixtures or electric wiring, discomfort and danger to life are likely.
13. Proximity of tenement to factories may mean poisoning of the air by chemical gases, mineral dust, or soot.

2. Levy, Julius, M.D.: Reduction of Infant Mortality by Economic Adjustment and by Health Education. Paper read before the National Conference of Social Work, Atlantic City, June, 1919.

3. National Conference of Social Work, 1919. Monthly Review, U. S. Bureau of Labor Statistics, July, 1919.

A little country school house in a neighborhood forty-five miles from medical aid and practically isolated in winter. Depends upon county medical supervision for health guidance.

This is an isolated school with four pupils, three in need of medical care, where the county health message became 100 per cent effectual.

MEDICAL INSPECTION IN BIG HORN COUNTY, MONTANA

By W. A. RUSSELL, M.D., County Medical Officer, Hardin, Mont.

In the belief that the methods previously employed by the health department were primarily wrong, we persuaded our county commissioners to adopt the more modern conception of disease prevention through educational methods rather than a dependence upon control by quarantine after disease has developed. For our educational health campaign we are furnished a baloptican for the projection of suitable pictures and a miscroscope to demonstrate to the parents and children that cell and germ life is not a theory, but a reality.

Object Lessons in Sanitation

Thus equipped, we go out over the county and examine the children for defective eyes, hearing, teeth, adenoids, or enlarged tonsils. Each child is weighed and measured. If time permits, the microscope is used to give the children an idea of cell and germ life, after which we usually catch a fly and show the filth on his feet, and his wonderful eyes. We are then ready to discuss freely how disease germs are carried from infected places and open toilets to the food, thereby causing disease.

In some instances two or three schools combine for these health demonstrations and the parents come with well filled lunch baskets. After a hearty picnic dinner we use the miscroscope to demonstrate to the parents anything which will be of practical benefit to that neighborhood. We discuss with them such questions as the home care of influenza patients, the diagnosis of spotted fever, the treatment of rattle snake bite without the use of whisky, and other timely subjects.

A clinic is held for the defective children, and discussion with the parents brings out what can be done to remedy the defects disclosed by the physical examination. Last year, out of fifty-two children with defective eyesight, twenty-six were fitted with glasses.

Reach the Isolated Districts

Picture No. 2 shows a little country school house on the top of the Rose-Bud mountains, where fifty-eight parents and children came to discuss better health and better sanitation for the neighborhood. They are situated forty-five miles from medical aid and, being practically snowed in during the winter, they must depend upon themselves. Anything the public can give them along the line of education and health is much appreciated.

In 1917, when we first started this work, we visited a school where the purpose of a school yard had been misunderstood, and thirteen horses and four colts were running loose in it. The outbuildings were in a deplorable condition and the school yard, which should have been neat and clean, was nothing more than a veritable barn yard. The children rolled and played in the filth, then came in and ate their lunches without washing their hands, and with good reason for there was not a drop of water on the premises with which to wash their hands or even to drink. The school board received a very plain talk from the Health Officer. The next visit to the school showed conditions somewhat improved, but some antagonism still existed. That evening we put on an illustrated lecture on sanitation and how flies spread disease. After it was over, one of the farmers was heard to remark that he thought that lecture was somewhat exaggerated, as they had always had flies at his house and none of the family had died yet.

Immediate results from a health talk. After a demonstration of the danger the children in this rural school in Montana immediately banked up the toilet, making it fly proof.

This group had no sense of community responsibility for health conditions until the county work brought it home to them. In two years antagonism was transformed into cooperative enthusiasm for local betterment.

In 1919 we again visited this school, but with a difference in our reception that demonstrates the value of the work. Every parent came out, watched, and discussed the examination of the children, after which a picnic dinner was enjoyed. This was on a Friday afternoon, and on the following Monday two of the children were taken to Sheridan, where one had his tonsils removed and the other was fitted out with glasses.

One day by special request we made a trip up into the mountains to visit a little school with only four pupils. Of these four, one had defective eyesight, one had enlarged and diseased tonsils, and one was sadly undernourished, possibly in the first stages of tuberculosis. We spent the entire day with those pupils and their teacher, and count it as one of the most profitable days we ever spent in health work, as we seemed to open up a new world to them by use of the lecture and miscroscope.

During the year of 1919 there were only thirty deaths in the county among a population of 7,000 white people; and there were no deaths from typhoid fever, tuberculosis, or preventable bowel diseases in children under two years of age. This makes the death rate for Big Horn County only four and one-half per thousand for 1919, which is as low or lower than any county in the state of Montana.

This is only a glimpse into the inside workings of the health department of Big Horn County, but it is accomplishing definite gains for health and is arousing a real community interest in health conditions.

A HOSPITAL AND HEALTH SURVEY

By HOWELL WRIGHT, Secretary, Survey Committee, Cleveland Hospital Council Hospital and Health Survey, Cleveland, O.

Hospital and health activities have a common purpose. It is better public health and fewer preventable deaths. There are four fundamental contributing factors to the efficient work of all hospital and health organizations working to this end. These are: (1) Development of medical education, both post graduate and under graduate. (2) Development of nursing education, both general and special. (3) Advancement of public health and preventive medicine. (4) Care of the individual sick. Due consideration must be given to each of these four factors in considering the work of any individual hospital or health organization or group of such organizations or community hospital or health needs.

The work of this Committee may be divided into two parts:

Part I.—A survey and study of the existing hospital and health facilities,—public or private, of Cleveland. It should determine the contribution which is now being made to the common end by the different institutions individually and collectively; discover ways in which these institutions may be made to contribute more by reasonable changes either in the division of labor with other institutions, the volume of work done or contemplated, or in the way of doing the work. This involves a study and survey of:

(1) Medical education in Cleveland as at present conducted.

(a) Use of clinical material and facilities in Cleveland; by the medical school for under graduate instruction; for post graduate instruction of young medical men; and for instruction and development of the medical profession in general.

(2) A study of the nursing education as conducted at present in Cleveland.

(a) Training schools giving general nursing education.

(b) Facilities for providing nurses with special education and training.

(3) The Department of Public Health and the city of Cleveland and its relation to the hospitals, dispensaries, and other medical institutions, and the profession in general; its activities in the care of contagious diseases and in preventive medicine.

(4) A study of the present existing hospitals and their plans for extension to determine

(a) The available and contemplated facilities for pay or private room patients; part-pay and ward patients; and free patients.

(b) The probable normal needs of the community for each of these classes of accommodations.

(5) A study to determine the present and contemplated facilities as well as the probable normal needs of the city for the care of certain classes of sick: Contagious, including venereal diseases. Acute surgical. Acute medical. Chronic, surgical, and orthopedic. Chronic, medical. Convalescent. Insane and mental diseases. Aged and infirm. Maternity cases. Babies and children. Accident and emergency cases.

(a) The immediate development of facilities for such patients as means of saving hospital space.

(6) Dispensaries. A study of their location as to their availability to all Cleveland citizens in need; the type of cases receiving treatment therein; the facilities of the various dispensaries to do properly the work undertaken.

Part II.—The second part is a more extended study of the community to determine the ideal number, grouping, location, character, and functions of the hospital, medical, and health institutions which can best serve Cleveland at present and during the reasonable future development of the city. This entails the following:

(1) Morbidity accident and mortality rates for the city, as a whole, and by districts, based on city statistics, questionnaires to doctors, hospital and dispensary records, Industrial Commission reports, United States Census figures on occupations, races, and ages, and morbidity censuses in other cities, perhaps house to house canvass of selected districts to learn amount of sickness, total and classified.

(2) Care secured by the sick. Economic ability to secure care. Home conditions affecting care. Knowledge or ignorance of existing facilities. Effects of agencies to reach those needing their care. Constituencies of various hospitals or attraction of hospitals for various groups. Survey of adequacy of home care in typical neighborhoods.

(3) Capacity and facilities of existing agencies for giving the amount of remedial care shown to be needed by studies of the amount and present care of all sickness, accidents, and by prospective increase of population.

(4) The estimate reduction in sickness from extension of preventive medicine and health insurance, based on European experiences.

(5) The medical school's relation to present and future hospitals, dispensaries, sickness prevention, and the health department.

(6) The relation of nurse training schools to present and future hospitals, dispensaries, sickness prevention, and the health department.

Canadian Public Health Association

The ninth annual meeting of the Canadian Public Health Association is to be held in Vancouver in June, 1920. The Canadian Medical Association will meet at the same place at the same time.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

MINIMUM STANDARD OF THE AMERICAN COLLEGE OF SURGEONS

THE superintendent, the staff, and the trustees are willing and eager to make their maximum effort for any patient in the hospital. That fact is true in almost every hospital on this continent. But do the superintendent, the staff, and the trustees coordinate their efforts so that every patient really gets the benefit of their combined energy and intelligence? In the terms of the stock market, that question is "prime stuff"; and it is just this question which the American College of Surgeons asks. The "Minimum Standard" penetrates through the complexities and reaches the heart of the matter. It is undebatable and is probably the most vital document which has come to hospitals in many years. Any hospital which does not meet that standard today has work to do. The standard is as follows:

1. That physicians and surgeons privileged to practise in the hospital be organized as a definite group or staff. Such organization has nothing to do with the question as to whether the hospital is "open" or "closed"; nor need it affect the various existing types of staff organization. The word staff is here defined as the group of doctors who practise in the hospital, inclusive of all groups such as the "regular staff," the "visiting staff," and the "associate staff."

2. That membership upon the staff be restricted to physicians and surgeons who are (1) competent in their respective fields and (2) worthy in character and in matters of professional ethics; that in this latter connection the practice of the division of fees, under any guise whatever, be prohibited.

3. That the staff initiate and, with the approval of the governing board of the hospital, adopt rules, regulations, and policies governing the professional work of the hospital; that these rules, regulations, and policies, specifically provide:

(a) That staff meetings be held at least once each month. (In large hospitals the departments may choose to meet separately.)

(b) That the staff review and analyze at regular intervals the clinical experience of the staff in the various departments of the hospital, such as medicine, surgery, and obstetrics; the clinical records of patients, free and pay, to be the basis for such review and analyses.

4. That accurate and complete case records be written for all patients and filed in an accessible manner in the hospital, a complete case record being one, except in an emergency, which includes the personal history; the physical examination with clinical, pathological, and x-ray findings when indicated; the working diagnosis; the treatment, medical and surgical; the medical progress; the condition on discharge with final diagnosis, and, in case of death, the autopsy findings.

5. That clinical laboratory facilities be available for the study, diagnoses, and treatment of patients, these facilities to include at least chemical, bacteriological, serological, histological, radiographic, and fluoroscopic service in charge of trained technicians.

"It has been the boast of the medical profession," says *The Lancet*, of January 10, 1920, in stating that no schools of rational psychotherapy have ever been established for the instruction of the student of medicine, "that improvements in the mental and physical hygiene of the race have been preceded by the discoveries of medicine. We must see to it that we lag not behind in our application of psychological methods to psychological disease. With a systematic initiation into the prevention, recognition, and cure of the earliest stages of mind diseases, the same proportion of our young graduates should turn their steps in the direction of psychotherapy as at present are attracted by any of the specialties."

THE NEUROTIC GIRL*

By JESSIE TAFT, Ph.D., Director, Department of Child Study of Seybert Institution, Philadelphia, Pa.

WHO is the neurotic girl? Neurotic is a term used very freely by lay persons as well as physicians, and frequently with a decidedly derogatory sense. I have heard broad-minded social workers as well as intelligent physicians say with a note of kindly contempt and complete finality, "Oh, she's just another neuro."

On the other hand, we read in psychiatric literature that the neurotic supplies a most valuable impulse forward in our civilization. He is the upsetter of tradition, the discontented, unadjusted element that refuses to accept old inadequate ways of doing things. Sometimes one wonders whether, if the repressions of the neurotic produce such creative results in art, literature, and social structure, psycho-analysis is not a bit rash in showing to the neurotic the way of normal living.

Maladjustments are modifiable through correct interpretation of the behavioristic reaction.

Many children who go to make up our incorrigibles could be saved by the public school.

It would mean teachers with a new psychology. It would mean more time to each individual child. It would mean small classes, more buildings, more teachers.

In the long run it would save money. Attention to neurotic children has to be given some time. If we refuse it early, they exact it later in our many institutions, in ruined homes and in wasted lives.

Adjustment on Basis of Handicap

Will adjustment mean loss of genius? We may comfort ourselves with the thought that not all neurotics are geniuses, and that the world stands to gain as much by the salvage of otherwise waste material as it may lose in the brilliant products of an unhealthful repression. Stevenson's genius may have been enhanced and his writings made more poignant by virtue of his lifelong ill health, but that will not prevent us from obtaining healthy bodies for our children if we can. Charlotte Brontë may have thrown herself more blindly and passionately into literary expression because of the impossibility of real satisfaction for any of her cravings and because of her ignorance of the character of those cravings, but we shall still believe in the evolutionary value of a growing mental health in our society made possible by a recognition of and conscious effort at adjustment and use of our instinctive life.

The pitying or contemptuous attitude of finality toward the maladjusted individual is equally hopeless for a mental hygiene program. If the label "neurotic," as is so often the case with the label "*dementia praecox*," prejudges the case in the eyes of the general practitioner, the social worker, and the public, why talk of mental health at all or of the possibility of influencing it for the better?

In discussing the problem of the neurotic girl, then, I am obliged to give not a medical diagnosis or list of differential symptoms, but a social definition in terms of behavior which we assume to be modifiable in greater or less degree. The question of presence or absence of constitutional basis must be ignored inasmuch as for our purposes it is immaterial. If there is a constitutional tendency toward instability, the altering of behavior will undoubtedly be more difficult. There is an ever present, unchangeable handicap, but improved adjustment on the basis of just this handicap is surely possible. For instance, a feeble-minded child has a constitutional defect, but, given that defect, it is still possible to find a level on which he can make a fairly good adjustment. His behavior is not necessarily bad because his intellect is defective. Because the neurotic individual has an over-sensitive, unstable, nervous make up, does not mean that he cannot learn to use it to the best advantage.

Social Response Object of Education

On the other hand, we must all admit that the line between the neurotic constitution and the normal constitution whose reactions have been developed along an unhealthy line by the peculiar combination of internal and external circumstances is an extremely hard one to define. It is far safer to ignore as much as possible the presence or absence of the organic basis and work on the concrete problems presented in the bad contacts which any given individual is making with reality. Now, see what has happened,—the term neurotic has lost all significance because our standard of measurement, that is, adequate or

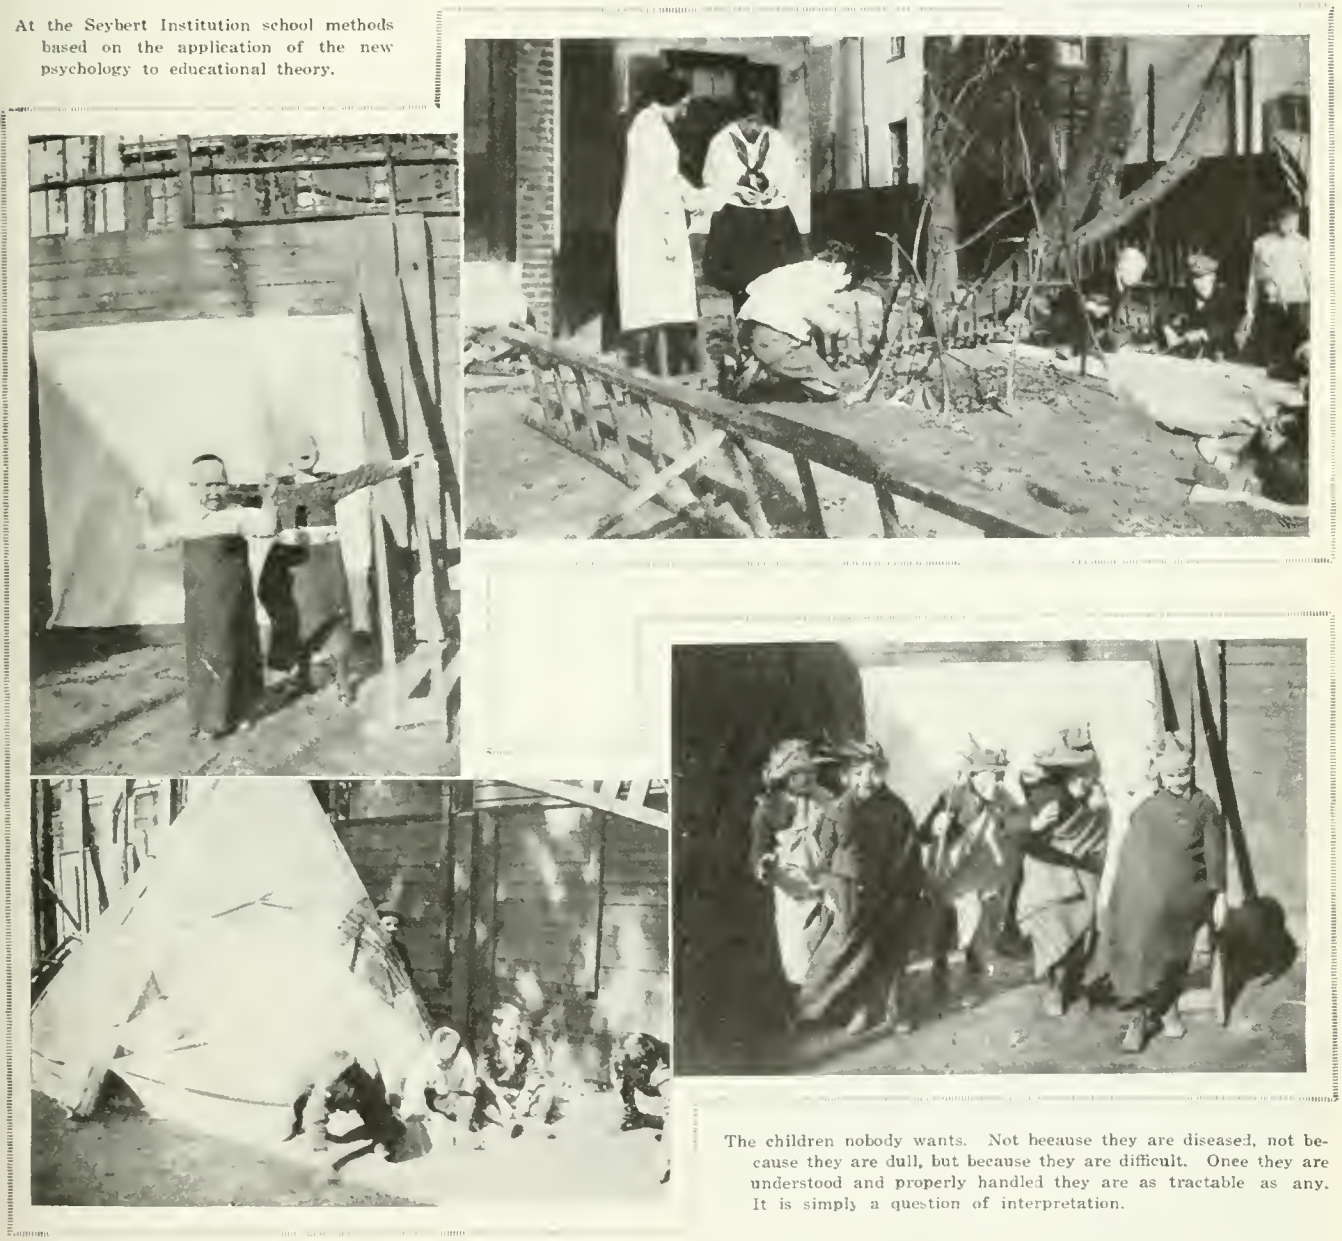
*Read before the International Conference of Women Physicians, New York, October 18, 1919.

efficient social adaption, applies to everybody, normal or abnormal. We need no longer worry about labels or diagnoses, the procedure is the same. The only question is: here is a person who is not making efficient contacts; how can he come to realize the cause of his difficulty? Or, if he is too young for that, how can we remove the causes so that he will naturally respond in a more so-

neurotic girl is always somewhat normal; at least, her mental machinery is at bottom of the same make, however badly she may be using it. Consequently, an environment and educational method which is peculiarly bad for the neurotic girl cannot be very good for the normal although the latter may have a better chance of surviving.

As I see it then, the question I have really been

At the Seybert Institution school methods based on the application of the new psychology to educational theory.



The children nobody wants. Not because they are diseased, not because they are dull, but because they are difficult. Once they are understood and properly handled they are as tractable as any. It is simply a question of interpretation.

cially desirable way? In other words, I find myself unable to differentiate between the problems that arise in the life of the so called neurotic girl and the problems that arise in the life of every girl. In consequence I am helpless to describe an environment and educational system which is good for one and not for the other. As I see it, the normal girl is always somewhat neurotic and the

asked to discuss is in what way can education and environment be made to solve the problems of mental health that are so acutely and conspicuously present in the life of the so-called neurotic girl, but are common to all, girls and boys alike.

It is obvious that what we have here is the whole great problem of a possible conscious control of mental and social life; the entire question

of whether social evolution is going to make mental health and social adaption as responsive to human desire and human needs, as it bids fair to make physicial health. Such a problem cannot be limited to any one group of people, like the psychiatrists, for its solution. It is a question with which society as a whole must eventually struggle. Just now, however, about the only light we have on the subject is coming from a comparatively small and modern group of psychiatrists. The psychologists, shut up as they have been until recently in their laboratories, have busied themselves with artificial problems or with the purely intellectual situation, and they are only now putting their theories to the test of every day life.

Certain groups of psychiatrists, on the other hand, have for a considerable period been struggling with raw human material, testing their theories at every turn by the actual changes produced or not produced in concrete behavior. It is not strange, therefore, that they have made revolutionary contributions to a new dynamic psychology which is based on modern biology and what it can tell us of behavior in lower forms of life. It is to this new psychology that we have to look for the solution of society's great mental hygiene problem. There is no other available. The academic psychology makes no difference to life and the older psychiatry holds before us only the finality of heredity and unalterable nervous structure.

Shall we, then, throw the burden of mental health upon the comparatively few psychiatrists and psychologists who understand this new psychology? Obviously this is impossible. Every family, rich or poor or middle class, has its mental hygiene problem and comparatively few of these problems are of so acute a nature as to lead them to the private office of the psychiatrist or to the mental clinic. And if they could all be induced to carry out such a program, psychiatrists, psychologists, and mental clinics would be hopelessly swamped. There are not enough psychiatrists or clinics to be more than a drop in the bucket when it comes to handling the problem of mental health for our young people. It is evident that others will have to take over the psychology which the psychiatrists have worked out and learn to use it before much will be done in improving environment and education for the nerotic or any other kind of girl.

I am not implying that we necessarily have to learn or practise any technic of psycho-analysis such as may be essential in curing the seriously maladjusted. I am talking only about a psychology of your human nature and mine, which is difficult solely because life is not simple, but which intelligent people ought to be able to grasp if they are capable at all of understanding their own mental processes. We all have the material, the proof of the theories as well as their substance within us. Should there be anything esoteric or mysterious about knowing the roots of our own behavior sufficiently to understand that of others, in order that what we attempt to do for them need not be so blind? We are bound to interfere with the lives of the young just by the mere fact of living with them and attempting to educate them. It is only a question of whether our contacts with youth shall be self-conscious and controlled. Must we leave psychological insight to be applied by the psychiatrist after the damage is done, or can we take over enough of it to prevent a large part of the damage?

The most difficult cases cease to be problem children when through behavior analysis and re-education they find a level to which they can adjust themselves. Plays of construction or of impersonation are of particular value.

The games at Seyhert Institution afford an unconscious expression of the personality of the child. The children are at all times fully occupied, and are always under observation to find the key to their maladjustment, and the psychologic moment for its correction.

Let us consider concretely the type of problem which is to be found over and over again in the life of the neurotic girl and see what social agency, institution, or professional group could be used to deal with these problems from a psychological

standpoint before they are so acute as to require the psychiatrist.

Resort to Mental Makeshifts

For the purpose of this paper, the neurotic girl is the girl who resists emotional maturity because every stage of growth demands additional effort to which she is unequal. The hold of the home, parental protection, infantile or childish dependence, and the childish methods by which she has satisfied her desires in the home situation have proved too easy, comfortable, and attractive. She will not or cannot without help meet the increasingly difficult problems of adult life on an adult basis; that is, seeing them as they actually are, and overcoming them by a practical and

The spontaneous reactions of children at play constitute the most fruitful field of study for the interpretative psychologist.

direct handling of the elements involved. She faces adult problems only by deceiving herself as to their real nature. She puts up a defense which is her way of meeting the situation. She protects herself from the truth by a make-believe adjustment. We may expect to find this breaking down of adjustment anywhere along the line of development of the ego instinct or the sex instinct and, accompanying it, a sense of inferiority in all kinds of disguises which is probably both cause and effect.

A real inferiority which the girl cannot accept, overcome, or compensate for may account for the clinging to childhood and the inability to put forth the effort required for growth. Repeated failure to adjust will then only increase the sense of inferiority. On the other hand, sneers, ridicule, or misjudgment of adults may prevent compensation for a natural inferiority and heighten the inability to face reality. Failure may also follow attempts to adjust to too difficult external circumstances, and produce a sense of inadequacy which again in a vicious circle discourages the effort to make new adjustment. The old infantile and childish methods of obtaining satisfaction, within the sheltering domain of the family, seems

Play activities are planned to promote normal reactions, and every effort is made to understand the mental needs of the child.

to the neurotic girl the safe sure way and, for fear of losing these valued-assured satisfactions, she hesitates to attempt to gain adult satisfactions that must be reached by perilous untried paths.

Social Worker Applies New Psychiatry

This girl whom we label neurotic is to be found everywhere; in the families of our friends, employed on our office staff, working in our kitchens, studying in our schools, being reformed in our reformatories, occupying the chairs in the doctor's waiting room, filling the case records of the Charity Organizing Society. She cannot be confined to any one class. What can we do with her practically in the immediate present. Of course, we know that the ultimate solution of the problem lies in educating the parents. The difficulties of the neurotic girl all go back to the home and relationships to father, mother, brothers, and sisters. If fathers and mothers understood and practised the new psychology, the millenium of the mental hygiene movement would have arrived. In the meantime, while we keep the home in mind as our final goal, what agencies outside the home can be used here and now to help the neurotic girl to grow up?

A comparatively recent movement in this country which has received a tremendous impulse from the war and which promises to be of untold value for any mental health program, is the coming together of psychiatry and social work in what is known as social psychiatry. Out of this has grown a new kind of social worker; at least she has a new name, the psychiatric social worker or the psychiatrist aide. Her place is in the parole department of a hospital for the insane, in the parole or out-patient department of a psychopathic hospital, and in the psychiatric clinic. She brings to this new field, a previously acquired technic in family case work, such as is used in

the Charity Organization Society. Social case work in the technical sense means not a giving of relief to the poor,—relief is only incidental and frequently detrimental to good case work,—but a method of assisting families and individuals in them to make more satisfactory social adjustments

Social Aides in Mental Clinic

You can see that the case worker has the same problem as the psychiatrist, the problem of finding some way to improve unsuitable behavior in the human being. The psychiatrist has approached the problem from the standpoint of the personality of the maladjusted individual, of the psychic factors, which unrecognized, have determined the particular form of maladjustment. The case worker, on the other hand, has tended to see the individual more as part of a family, a neighborhood, a city, a nation, and to interpret his maladjustment in terms of the effect of the social and economic environment upon him. The psychiatrist has sought to alter behavior through analysis and re-education of the entire mental life of the individual. The case worker has tried to change behavior through improving the physical, economic, and social conditions in which the individual has been living. The good case worker, like the good psychiatrist, has accomplished her results as far as possible through the aroused interest, intelligence, and initiative of the maladjusted individual himself.

The limitations of the two methods, the need of each for the other, is apparent and in their union in the social service department of the psychiatric clinic and hospital we have a powerful instrument for getting at the neurotic girl. The psychiatrist can use the social worker to multiply his usefulness and influence many times. She takes over from the psychiatrist the psychological interpretation of the case, which she lacked before, and, combining it with her knowledge of social conditions, is often able to bring about concrete results in the lives of clinic patients which neither she nor the psychiatrist could have accomplished alone. Remember, I am not talking about private practice, although it may be that even there the psychiatrist could use the social worker to advantage. I am talking about all those centers where the psychiatrist tries to handle large numbers of cases and cannot give to each the individual attention required. The chief hope for the class of girls who must use mental clinics because they can never afford to pay the psychiatrist for individual attention is thus far the social workers who, because they are more numerous, less specialized, and their time less valuable, can afford to go into the details of the girl's life outside, remove the worst obstructions, and patiently help her to understand the reasons for her difficulties.

A New Interest in Psycho-Analysis

The failure of the mental clinic thus socially equipped is that it will never at its best reach more than a limited social group, and of these usually only the more advanced and troublesome cases. However, this is not the whole story. Already a secondary result of this wave of social psychiatry has been felt which bids fair greatly to enlarge the field of influence of the new psychology. When the pressure of the war created a demand for case workers with a knowledge of psychology and mental disease, courses in social psychiatry sprang up in the training schools for social work in Boston, New York, and Philadelphia following the emergency summer course at Smith College in 1918, which has since become permanent. All this publicity about social psychiatry and the psychological or psychiatric approach, as well as the burden of training the students in these new courses in practical case work which fell quite heavily upon the Charity Organization Societies, opened the eyes of the ordinary case workers and of the regular training schools to the fact that practically every case work problem is psychological and, if the psychiatrist has anything in the way of a practical psychology, it is needed for every day use quite as much as for the clinic patient.

The workers already on the staff of the Charity Organization Society in New York and Philadelphia began to ask the training schools for courses which should give *them* a chance to learn the psychiatric method. The response to this demand was immediate. The New York school instituted a permanent department under Dr. Bernard Glueck. This department provides a seminar course to which the practising social worker can bring her case work problems for discussion. In Philadelphia the training school gave a six months lecture course in social psychiatry which was attended by the forty members of the Charity Organization Society staff and representatives of nearly every social agency in Philadelphia, and then instituted a permanent course under Dr. G. Stanley Abbot. Some one who reviews all of the case records of the Charity Organization Society in Philadelphia recently made the comment that nothing in the history of the Society had ever made such a change in the attitude of the workers as this influx of the new psychology. With Boston I am not so familiar, but I know that courses were given there and the

influence of the Psychopathic Hospital was greatly extended. The results of this awakening of social work, in the East at least, were seen clearly in the National Conference at Atlantic City. Mental hygiene, social psychiatry, the new psychology, swept through the conference. One heard it on every side.

Physicians Solve Social Factors

There is no doubt that from now on the case worker equipped with a better psychology is going to be a powerful instrument for straightening out the neurotic girl who is constantly appearing in her work. To her comes the girl who is a problem in the home because she will not attend school or is in constant trouble at school; the girl who finds the transition from school to work a crisis and is unconsciously evading economic independence, by losing her job repeatedly, finding something seriously wrong with every position she tries, or developing physical symptoms which keep her from working steadily; the girl who is just beginning to enter a career of delinquency, as a thief, or a sex offender. With this kind of girl, whom the psychiatrist has not time to treat, the case worker who has some understanding of the unconscious mechanisms back of her behavior, may make a genuine contribution to mental hygiene.

We must realize, however, the limited group thus reached. The case worker after all comes in contact with a comparatively few families and under present conditions her work is likely to be confined to families where poverty is a factor. There remains the large mass of the population, the average middle class as well as the wealthy, whose mental hygiene needs are equally pressing. With a single exception, it seems to me the physician in general practice is the most important and as yet comparatively the least used agent for conscious mental health in our social structure. Particularly is this true of the woman physician who is peculiarly fitted by inclination, interest, and the character of her patients for dealing with the problem of the neurotic girl. All that she needs is to have her attention diverted from the purely medical issues and awakened to the social and psychic factors in the illness of the neurotic and the possibility of doing something not merely palliative, but constructive, with this type of patient.

Because the neurotic girl always develops physical symptoms as critical situations are forced upon her, whatever her station in life, she is practically sure to find her way to the general practitioner and as there is often a question of some disorder involving the sex organs the physician selected is frequently a woman. The very fact that the girl seeks the help of the physician, that there is a concrete physical difficulty to discuss, that the physician is in the confidence of the girl and the family, and is often able to educate the family regarding the treatment of the girl, makes her position in the solving of this problem absolutely critical.

Complex Elements of Inadequacy

The woman physician can often help to loosen the hold of the neurotic father or mother blindly keeping their daughter attached to the home and making emotional maturity almost impossible for her. She can get at the unsatisfied sex life of the parents, unconsciously trying to compensate for its losses by exacting an extreme response in the love of the child. She can point out to the parents the need of the girl to become economically independent, no matter how well to do the home. Receiving as she usually does the complete confidence of the girl, she can easily and naturally point out the inferiority, real or imagined, which is at the bottom of the trouble, show the parents how their attitude toward the girl has reinforced her sense of inadequacy, and teach both girl and parents how the weak spot may be strengthened by facing it and slowly training it into efficiency; or how it may be compensated for by a strengthening along other lines and a simple acceptance of that particular defect.

I wonder how many of us realize unless it has come home to us in our own lives what a handicap a simple physical inferiority or belief in general physical inadequacy may become. I have in mind a girl whose physical make up was fairly adequate but as a very little child she was clumsy, pigeon-toed, and inclined to be afraid to use her body. Her parents laughed at her attempts to walk and run and at her frequent falls. They exaggerated her timidity and encouraged her not to try any unusual physical feats. There was no gymnasium work in the schools she attended. She grew very rapidly and at twelve was far too large and heavy for her age. Children called her fatty. Her mother said great big girls shouldn't run about like tomboys, but sit still and be lady-like. Her consciousness of her physical ineptitude increased to a painful extent. She took part in no sports or games that would betray her weakness. She was in deadly fear of walks, because there might be fences to climb. She dreaded the simple feat of climbing in and out of wagons. This lack of confidence extended to every part of her life. She was sure no man would ever care about her. She compensated in an over-development of intellectual interests, but even here she had not the

confidence that her ability warranted. Middle age finds this girl just beginning, through analysis of her own behavior, to get a legitimate self-confidence intellectually and socially and the free use of her own body, which wasn't particularly inferior after all. This particular girl had enough energy and ability in other lines to fight her way through her sense of physical inferiority; but what might such a handicap not do to the less hardy nature.

There is nothing in such a situation that could not be handled by anyone with interest and psychological insight. The woman physician meets just such inferiorities and many more subtle ones every day. The new psychology can save the energy wasted in concealing these inferiorities, and restore the individual to normal self-confidence and usefulness.

Mass Methods Must Fail

On the sex side of the resistance to maturity the woman physician undoubtedly can be of the greatest assistance in reconciling the neurotic girl to the idea of normal sexual development. I think we often make grave mistakes in our programs for sex education by confusing knowledge of the facts of sex with emotional adjustment to those facts in real life. We assume that the home, the friends, social opinion, and custom as the girl knows them have toward these facts the same wholesome sensible feeling that we who are giving the instruction have, or ought to have. We presuppose that the girl's social environment has done nothing but repress the facts, and all that is to be done is to see that she gets them simply and scientifically. The thing we overlook is that the environment has bred in the girl an emotional attitude toward the very facts it has concealed and that attitude is usually made up of horror, curiosity, disgust, and fear. To the girl with such an innate attitude, knowledge of the facts may only increase the horror and curiosity, and produce an added emotional resistance.

One of the most difficult girls in my experience was a Jewish girl of sixteen. She dressed, acted, and looked like a child of ten. Every effort was obviously toward the refuge of childhood. She had every kind of nervous symptom; jerked, twitched, became hysterical if upset. She would be unable to talk at all for an hour or more at a stretch. She ate in the most childish, erratic way, usually choosing milk, or ice cream, or sweets. When, after months of social supervision and removal from her home, she finally loosened up sufficiently to tell her story, it developed that she had been familiar with the ordinary expressions of sex from the age of four or five and had tried them all. Every conscious attitude toward it was conventional. Her disgust and horror were equalled only by the attraction it had for her. She had the physical and sexual development of a woman, but she clung fiercely to the idea of innocent childhood. Whenever her interest in sex got the better of her, as it frequently did, and she flirted with the elevator man or went out to Coney Island and let herself be kissed, the conflict between her two attitudes would result in an hysterical attack. She did not know anything about the scientific facts of sex and she did not want to. Once I tried to give her sex instruction. I talked to a deaf mind. A year later she asked me in a confused way if I had ever told her anything about such things.

Facts could mean nothing to such a girl. Only an emotional reconciliation between her own sexual needs and the kind of social morality with which she was familiar could have availed to save her. Her constitutional instability, the terrible home conditions, and the length to which her maladjustment had gone, made her case almost hopeless and yet there was about the girl something intelligent and fine which kept us working at her. She has managed to stay out of the hospital; she has learned to work a few weeks at a time; and she understands in a measure the character of her conflict. After two years, I met her, and was completely dumbfounded by the degree of insight she had acquired. It was then that she asked for and for the first time seemed to understand the plain facts of sex. She is not one of the hopeful cases and is very probably not worth the time we have spent on her, but she illustrates in exaggerated form the kind of conflict that the woman physician can help settle for the neurotic girl, by virtue not so much of her knowledge as of her own emotional adjustment to sex.

The moral of this tale is that teaching sex by the mass method is a doubtful procedure if it cannot be followed up by the most careful individual help to the girl who has a problem. The safest way is to give the essentials of sex, with no special emphasis, in the natural place in school, either in biology or physiology. Then the case work method must be used to meet the emotional conflicts, and nine times out of ten the woman physician will be the one who has the opportunity to help make the adjustment.

Mental Hygiene in Public Schools

There is one last agency for the salvation of the neurotic girl still to be considered. It is the most important and the most unprepared for the task of any except the home. The school reaches practically every child and does its part in deepening or lessening the neurotic tendencies. At

present we are safe in assuming that for the most part it deepens these tendencies. It drives the neurotic child into truancy, vagrancy, anarchy, invalidism, and every form of delinquency; or hardens its emotional reactions into permanent moods and it does all of this without in the least being aware of it. I do not doubt that there are many good schools and good teachers, but for the most part they are intuitively good, not consciously so, and in our large cities where the tremendous flood of children almost overflows the machinery, the necessity for an ironclad system to make things go at all tends to kill any enlightenment the principals and teachers may possess.

If our public schools really educated, if they understood that education involves a training of the instinctive and emotional life as well as of the intellect, if they saw that they cannot even develop intellect as long as they ignore desire, we should have an agency for adjusting the neurotic girl and boy second only to the home in its power. There is proof for this statement. Enlightenment is coming into education in spots. There are visiting teachers who work on the problem children in a school and get wonderful results. There are experimental schools whose methods are based on an understanding of the new psychology as it applies to educational theory. These schools are able to deal with the able but neurotic child who cannot get along in the public school. Those of us who work with difficult children are defeated constantly not so much by the impossibility of the cases as by the impossibility of finding any public school that understands or has time to act on its understanding. I am constantly trying to straighten out the children the public school can't handle. Our school[1] is not primarily educational but is a place to observe and get acquainted with difficult, dependent, or destitute children whom the various children's agencies of Philadelphia are trying to place satisfactorily in homes. They are children who do not get along anywhere. Nobody wants them because they are so hard to manage. The thing that constantly surprises us is how easy it is to change their behavior. They are not set like adults; and a little understanding, a little insight, and patience, a mere approach to real educational methods, often gives immediate results that are almost like magic.

May I tell you about Nick? Nick is an Italian boy of twelve; he lives in an Italian neighborhood and speaks only Italian at home. His mother is a good soul but utterly foreign and untouched by American ways. This makes her inferior in Nick's eyes. His ideal is the American way of doing things. Nick adores his mother but tyrannizes over her, and her only method of controlling him is to scold, nag, and cry. She is powerless against the forces that have taken hold of Nick. Nick is a real person, a born leader, with charm and force. At school Nick has to go in classes with little boys because he hasn't mastered the English. He doesn't understand what is said half the time but will not admit it. English is like a barrier between him and school. He is always in a position of inferiority and he hates school in consequence. Nick is too aggressive a person to accept this. He plays truant and exercises his power where he can be superior in use of his fists with a gang of boys, in carrying out mischief. Here he can feel comfortably powerful and at home. The more delinquent Nick becomes, the more his mother threatens to put him away. Nick is terrified at this idea and is afraid of every strange person who comes to the house. He is hardly ever at home, but runs loose like a hunted thing. The social worker tried to get him to our school. He refused to come,—resisting every persuasion in blind fear. Finally, we went with an auto early enough in the morning to find Nick still in bed and, making a virtue of what might become a necessity, he reluctantly consented to come.

Instincts Subject to Training

From the moment Nick got acquainted with us there has been a growing change in attitude. We did not begin trying to make Nick study out of books, but we admired greatly his successes with clay and reed. We did not say too much about his tendency to knock down whatever happened to be in his way, often some small unoffending youngster. At the mention of a book or lesson Nick shied like a young colt. We bided our time and put all the emphasis on achievement in hand work and interest in nature. Soon Nick's desire for superiority began to be a little appeased by his successes and he used fists less and began to pine for new fields to conquer. He became interested in stories and pictures. Inadvertently he got so interested one day he tried to read. We seized the psychological moment and praised his efforts. He was told that he could do just as well with his head as with his hands if he had the patience. Ever since Nick has plugged away on books. His absorbing interest in making things has been transferred to book learning for the time being. Nick is apparently a reformed character, but we don't dare send him back to public school because they would not understand or make any allowance for Nick's need to succeed.

Russell is a boy who is timid physically, the

1. Seybert School for Child Study, Philadelphia, which is associated with the Children's Bureau and the Temporary Shelter of Philadelphia.

butt of the other boys, and I suspect, inferior intellectually. He seems to have compensated for his weakness by developing a vocabulary whose foulness is exceeded only by its variety. He dares to call anyone from the teacher down any name he can think of and for the joy of exercising this power he endures the beatings given by the other boys. Russell shuns everything approaching school work. The very sight of a school room calls forth streams of abuse and threats of violence. To get along with Russell you have to be infinitely patient and perfectly indifferent until his own curiosity overcomes his resistances. Once we can find something Russell can do well, a chance to approve of him without arousing his suspicious antagonism, we think we can manage him. In the meantime, we let him wander around by himself and we ignore his language. One success has been achieved. The third day at school Russell worked on a basket for several hours at a stretch. We are just waiting.

Many such children, who make up our incorrigibles, could be saved by the public school. It would mean teachers with a new psychology; it would mean more time to each individual child; it would mean small classes, more buildings, more teachers, and a great deal more money; but in the long run it would save money as well as children. The attention has to be given to neurotic children some time. They make us pay for refusing it earlier, by exacting it later, in our many institutions, in ruined homes, in wasted lives, and squandered energy.

There is surely no program for social betterment which is so worth a life time of effort and interest on the part of the medical profession as a mental hygiene program which has for its goal the use of the public school system to develop the child, neurotic or normal, into the best adjusted human being that he is capable of becoming.

TO DIRECT RED CROSS WORK

Dr. H. C. Garwood, associate superintendent of the Pittsburgh city schools, has been appointed European director for the junior Red Cross, succeeding Major Royal S. Haynes, and will sail early next year for Paris headquarters. The after-war program of the children's organization includes relief and rehabilitation work.

FILLING IN THE GAPS OF CHILD LIFE

Child welfare work in New York directed especially toward the control of the appalling loss of infant life in the colored districts of New York is reported in *The Survey* of December 27, 1919. Two great needs are emphasized: the need of adequate facilities for the treatment of defects, and the need of thorough medical examination and diagnosis for the pre-school child. Great gains have been made in linking up the community with every facility provided, but facilities for the treatment of nose and throat troubles are notoriously inadequate and so widely scattered as to be difficult to reach. The problem of defective nutrition is met through nutrition classes for the correction of the food habits of the children. The nutrition classes are supplemented by work with the mothers with practical demonstrations in the preparation of foods beneficial to the children.

WOMEN SEEK CAREERS IN SCHOOL OF OCCUPATIONAL THERAPY

By MARGERET NEALL, Secretary, Philadelphia School of Occupational Therapy, Philadelphia

The Philadelphia School of Occupational Therapy was founded by the National League for Women's Service in the summer of 1918. As its object was primarily patriotic service, it was financed for its first year by the War Chest, two classes being graduated during the year. These four-months courses trained about fifty women to carry on the work in military and civil hospitals. Two art schools of the city offered the use of their class rooms and faculty as a war service, the first class dividing its time between the School of Design for Women, and the School of Industrial Art, the second class being concentrated entirely at the former. Its success, as measured by the constantly increasing demand for its graduates, a demand that far exceeded the supply, warranted a building of its own, so a suitable house has been obtained and all classes are now held under one roof. The present location of the school is in a desirable residence portion of the city. Special attention has been paid to making the working conditions not only healthful, but attractive. The small garden at the back of the house is under the care of the Society of Little Gardens, and many plans are on foot for its development next spring. A committee of students, working under the House Committee, arranges a hot lunch, which is served daily in the school. The class is a self-governing body, conforming to the general rules of the school.

Products of Occupational therapeutic work from the Philadelphia School of Occupational Therapy. Short of actual drudgery, the patients do better when occupied on useful products. The work must interest them, and must bear a definite relation to the disability it is calculated to correct.

Students from out of town are helped and advised in their choice of boarding places. Graduates are encouraged to keep in touch with the Dean, and to confer with her when changing positions. In this way she has already been able to place in civil work those whose terms in the military hospitals have expired.

Since this is the period of adjusting the military use of

Occupational Therapy to the needs of those industrially handicapped, the course has been kept as flexible as possible, and is constantly being broadened to meet the new conditions. The members of the faculty keep in intimate touch with the needs of hospitals and sanatoriums, and the good equipment makes technical development possible. The class rooms are bright, well ventilated, and cheerful.

Students from the Philadelphia School of Occupational Therapy instructing patients at the Pennsylvania Hospital for Nervous Diseases.

The first and second classes, owing to the war necessity, received the most intensive training consistent with efficiency. The hospital practice, lectures, and craft work were condensed into four months. The course under present conditions takes eight months, and several additions have been made to the curriculum. To its therapeutic side has been added a course in anatomy and kinesiology, and to the occupational side, work in leather and cement.

As suitable personality plays such an important part in the success of an occupational aide, the Directors reserve the right to refuse admission to any applicant, or to grant admission only on probation. Applicants for the course must be at least nineteen years of age, while those over thirty must show special ability, or some special accomplishment. No applicant is accepted without a physical examination by the physician of the school.

Workers Fully Accredited

A student successfully completing the course receives a certificate, and, although the School does not guarantee positions to its graduates, so far the demand for aides has been far in advance of the supply. At the present writing, applications for aides are on file from four hospitals and sanatoriums, and another hospital has notified the Dean of its need in the near future. Graduates of the school are now doing splendid pioneer work in developing departments of occupational therapy in the state sanatoriums for tuberculosis, its introduction into these institutions having been ordered by the State Commissioner of Health, Colonel Martin. Its influence upon the morale of these sanatoriums has been felt immediately, even by those who were most skeptical of its benefits.

The regular course includes hospital practice, lectures, and craft work; and we have been asked to arrange special classes to accommodate nurses who wish to add occupational therapy to their equipment in caring for the sick.

The cooperation of two of the leading hospitals in Philadelphia, the Philadelphia General Hospital and the Pennsylvania Hospital for the Insane, has insured the best hospital training. Under expert guidance the pupils of the school apply the theories of the class rooms in the wards and workshops of the hospitals. In this way they gain practical experience in teaching, and at the same time prove their ability for the work.

The lectures are given by well known specialists in the subjects treated, and a quizz at frequent intervals tests the standing and understanding of the students. The subjects of the regular course of lectures for 1919-1920 are as follows, with special lectures at varying intervals:

History of occupational therapy..Dr. Thaddeus Bolton
Consciousness and interest.....Dr. Thaddeus Bolton
Formation of habits.....Dr. Thaddeus Bolton
Treatment of defective speech....Dr. E. B. Twitmyer
Speech reading.....Miss Cora Kinzie
Mental diagnosis.....Dr. Thaddeus Bolton
Tuberculosis .....Dr. A. C. Morgan
Hospital etiquette.....Miss S. L. Clayton
Use of occupation in psychosis.....Dr. D. H. Fuller
Hysteria .....Dr. Thaddeus Bolton
Mental defects..... Dr. Owen Copp
Anatomy and kinesiology.....Dr. Thaddeus Bolton

Occupation Adapted to Need

Teachers who are specialists in the various lines direct the work in crafts. Much stress is laid on the fact that different disabilities are helped by different crafts. Classes include: (1) Weaving, hand, treadle, and cardboard loom. (2) Pottery, modelling, and cement work, toys in plaster. (3) Carving, wood construction, toy making. (4) Basketry, reed and raffia, chair caning. (5) Cord knotting, lace making, bead work, braided and hooked rugs, rake knitting. (6) Elementary bookbinding, cardboard and paper construction.

The hours are from nine until four, and the tuition fee for the whole course is one hundred dollars. Special arrangements are made to meet the requirements of special students, and, in learning any craft, the student is trained to think of it in the therapeutic as well as technical terms.

The following is a list of partial courses furnished by the school:

(1) Hospital practice, lectures, and some uncompleted crafts. Fee according to time for tuition.

(2) Hospital practice and lectures. Fee twenty-five dollars. Applicants must be accepted by Personnel Committee and pass a physical examination by the physician of the school. Must show certificate of work in crafts satisfactory to the faculty in order to be excused for crafts work. Certificate awarded to students satisfactorily completing the required course.

(3) Lectures. Fee fifteen dollars. Permission to attend must be obtained from Dean and faculty. No certificate given.

A small exhibit of student's work was sent to the annual conference of the Society for the Promotion of Occupational Therapy, held in Chicago last September, and later to a meeting of the State Federation of Pennsylvania Women at Scranton. The large exhibition of all the successful work of the students was held at the Art Alliance, and was then displayed by John Wanamaker in one of his show windows on Chestnut Street, where it attracted a great deal of attention.

The Board of Directors feels that this school supplies an ever increasing need in civil life. Not only the the hospitals and sanatoriums requesting aides, but demands come in for teachers of handicapped adults or children

who are not in institutions. Thus another field of usefulness is opened, that of the visiting aide.

Altogether, the outlook is a most inspiring one for the woman who is especially fitted for the work, and the school hopes thus to preserve one of the benefits left after the distress of war.

LAW FOR THE DOCTOR*

By LESLIE CHILDS, Attorney At Law, Indianapolis, Ind.

Validity of Contract to Furnish Patient Medical Services for Life

A careful search of the books discloses but two cases involving the legality of an agreement, between a physician and his patient, by which the former agreed to render medical services to the latter for life. The first is an English case, Dent *vs.* Bennett, 7 Sim. 539, decided about 1838, in which it was held that such a contract was void, as against good public policy. The reasons for this conclusion were stated by the vice-chancellor in the following language:

"It is plain that the existence of such an agreement is a direct premium to the medical adviser to accelerate that death upon the happening of which he is to have £25,000, and it is in vain to say that in fact it did happen that the party who was to give the £25,000 did live four or five years after the agreement.

"You must look at the agreement as it stood at the time it was made; and it must be admitted that the human mind is so constituted as that this agreement might be a temptation to some persons to do the very thing which it is obvious it was the duty of the party who took the agreement not to do; and my deliberate opinion is that it is totally void in point of law for that reason."

The second case referred to was the American case of Zeigler *vs.* Illinois Trust & Saving Bank Exr., 245 Ill. 180, decided in 1910, nearly a hundred years later, which may in a measure account for the opposite views entertained by the two courts. Though in justice to the earlier court, it may be said that the evidence of the claimant's good faith was not nearly so convincing, nor were his hands comparably as clean as were his prototype's in the Ziegler case in the following century.

The facts in the Zeigler case were substantially as follows: Dr. Zeigler, a practising physician and surgeon, in the city of Chicago, was employed professionally by Mrs. McVicker sometime during the fall of 1899. A few months later a contract was entered into between them in which it was stipulated that Dr. Zeigler was to be paid $100,000 out of her estate after her death; the consideration being that Dr. Zeigler should give her such medical attention as she should require during the remainder of her lifetime. At this time Mrs. McVicker was 78 or 79 years old. About five years later she died, at Pasadena, Calif., and, when the doctor attempted to enforce the contract, it was disputed by the executor of the McVicker estate.

Suit was filed on the contract; a judgment for the $100,000 was given the doctor in the Circuit Court; this was reversed in the Appellate Court, and the case was afterward taken to the Supreme Court for final adjudication.

The evidence was undisputed that the contract had been openly entered into after Mrs. McVicker had consulted a number of her friends; in fact, it showed that she had insisted upon the contract in the first place; that it was her idea; that she was a woman of education and culture, owning large property interests which she personally managed and supervised; in fact, an exceptionally shrewd woman.

It was also shown that the doctor attended her constantly during the period of the contract; giving her the right to his attention at all times to the exclusion of his other patients. In summing up, the Supreme Court said in part:

"It is urged that this contract is void chiefly for the reason that it furnishes an incentive to appellant (the doctor) to shorten the life of Mrs. McVicker by neglect, or improper treatment, or by the commission of the crime of murder. Each argument made by appellee (the executor) in support of this contention involves a breach of the contract, and is not founded upon the performance of it. It cannot be seriously contended but that, in order to comply with the terms of this contract and be entitled to receive the benefits of it, the appellant (the doctor) was bound to give Mrs. McVicker the best treatment within his power and skill, and to prolong her life as long as possible. There can be no doubt that a contract to commit murder or any other crime, is void, as against public policy. This contract does not contemplate the commission of a crime, or the doing of anything which is unlawful or contrary to good public morals. Even if it be conceded that the contract, under its terms, offered some incentive to appellant (the doctor) to commit a crime, that would not necessarily render it void."

Thereupon the Supreme Court reversed the Appellate Court, affirming the judgment of the Circuit Court. Holding that the contract was valid and binding, and that as the doctor had fulfilled his part of the contract he was entitled to the consideration, namely, the $100,000.

NEW YORK MEDICAL SOCIETY PRESENTS HEALTH INSURANCE REPORTS

The majority and minority reports of the Committee of the House of Delegates of the Medical Society of the State of New York, which was appointed in May, 1919, to study the subject of health insurance legislation, have been submitted. The reports are published in full below:

MAJORITY REPORT

At a meeting of the House of Delegates of the Medical Society of the State of New York, held in Syracuse, May 5, 1919, in compliance with the recommendations of President Halsted,

That before taking final action, the subject of compulsory health insurance be referred to this Body to a committee to study it with special reference to its relationship to the medical profession, and report back to a special meeting of the House of Delegates to be called in the fall before the next meeting of the Legislature,

the following resolution was passed by the House of Delegates:

In regard to that portion of the President's report having to do with the Donohue-Davenport Bill, we approve and advise the adoption of the recommendation made in supplementary report to the end that there be appointed a special committee named by the President to study the subject and report back to a special meeting of the House of Delegates, to be called this autumn before the next meeting of the Legislature.

The following is the Committee appointed by President Thomas H. Halsted: Harvey R. Gaylord, chairman, Buffalo; Grant C. Madill, incoming president, Ogdensburg; Thomas H. Halsted, retiring president, Syracuse; Joseph B. Hulett, president, First District Branch, Middletown; Frederick C. Holden, president, Second District

Branch, Brooklyn; Luther Emerick, president, Third District Branch, Saugerties; Thomas A. Rogers, president, Fourth District Branch, Plattsburg; G. Massillon Lewis, president, Fifth District Branch, Vernon; R. Paul Higgins, president, Sixth District Branch, Cortland; John H. Pratt, president, Seventh District Branch, Manchester; Albert T. Lytle, president, Eighth District Branch, Buffalo; J. Richard Kevin, chairman, Committee on Legislation, Brooklyn; Henry L. Winter, chairman, Committee on Medical Economics, Cornwall; Arthur W. Booth, member, State Board of Medical Examiners, Elmira; George W. Kosmak, chairman, Committee on Legislation, Medical Society, County of New York, New York; John A. Lee, chairman, Committee on Legislation, Medical Society, County of Kings, Brooklyn; James F. Rooney, chairman, Committee on Legislation, Medical Society, County of Albany, Albany; Walter H. Kidder, secretary, Medical Society, County of Oswego, Oswego.

The incoming president, Grant C. Madill, added to the Committee Sigismund S. Goldwater, medical director, Mount Sinai Hospital, New York.

Your Committee met at Atlantic City on June 10, 11, and 12; at Brooklyn on July 26; at Buffalo on September 3; and at Utica on November 9; and numerous meetings of sub-committees were also held. The members of the Committee have given good attendance, although two members have not attended any meeting.

Your Committee would like to offer the following brief résumé of the subject of its study before stating its recommendations:

The essential components of all compulsory health insurance schemes are two: (1) the provision of a cash indemnity during a relatively brief period of incapacity to labor due to illness; (2) the provision to the insured and their dependents during a determinate time of so-called medical benefits which comprise medical, dental, and nursing attendance, hospital and sanatorium accommodations, maternity attendance, drugs, and all necessary medical and surgical supplies.

The proponents of this legislation rest their demand for the institution of this scheme in America upon two main allegations: (1) that a very large amount of poverty is due to illness causing consequent unemployment and loss of income; (2) that a vast amount of the population receives inadequate and insufficient medical attendance; that is, that medical attendance is grossly deficient both as to quantity and quality.

With the general features of the measures proposed for the legislative enactment of the compulsory health insurance scheme in this state your Committee will deal only in the briefest manner; the matter is familiar to you. It is proposed to establish an administrative machinery radiating downward from a division of the State Industrial Commission composed of a certain number of commissioners appointed by the Governor who in turn appoint a chief of the bureau of health insurance. Subordinate to the Commission and acting under regulations made by the Commission function the boards of directors of the local funds composed of three members elected by the employer members of the local fund, three elected by the employees and one additional elected by these six. All the affairs of the funds are administered locally by these boards of directors. Each local fund employs a medical officer who is not permitted to practise and who is practically the medical supervisor of the administration of the benefits of the Act. The medical profession is not represented upon any executive body under the proposed law, but is permitted to function solely through advisory committees, local and state. Its sole statutory representative has an administrative, not an executive function.

After consideration of the evidence put forward by the proponents of this legislation in support of their statement that a large proportion of the poor have been impoverished through unemployment caused by illness, your Committee finds that none of this evidence is unimpugnable and that it rests upon largely *a priori* reasoning. The preponderance of evidence is against the fact that any considerable amount of impoverishment is caused by illness; moreover, in those cases where impoverishment is caused by illness, it is due to the long enduring disability preceding death occurring in the chronic diseases, especially tuberculosis, chronic heart disease, cancer, chronic joint infections, renal and vascular disease which cause a disability long exceeding the period of twenty-six weeks during which the insured is entitled to benefits under the scheme. The statistics of the Labor Bureau of New York state show that in the main disability from all causes, including accident, injury, and illness, is the source of, on the average, only 5.7 per cent of unemployment, about the same amount as that caused by weather conditions (5.6 per cent), or a little less than half that caused by labor disputes (10.6 per cent), or one-thirteenth that due to lack of work (74.6 per cent). A survey entitled "Poverty in Baltimore and Its Causes; Study of Social Statistics in the City of Baltimore," by the Alliance of Charitable and Social Agencies, McCoy Hall, Baltimore, Md., November 15, 1918, gives strong evidence of the small part illness plays in the cause of poverty; moreover, it evidences strikingly the fact heretofore stated as to the relationship of prolonged disability not covered in any scheme for health insurance to the relatively few cases of impoverishment due to sickness. Your committee would find, therefore, that short illnesses causing ephemeral disability bear no relation to poverty; that where impoverishment is caused by illness it is in all instances due to long continued disability; and that illness is but a very minor cause of unemployment as compared even to the conditions of the weather or labor disputes.

Your Committee is unable to find any available evidence that will bear inspection proving that, in the main, medical attendance in this state is grossly deficient in quantity or grossly defective in quality. If these facts were true it is unable to satisfy itself that the people of this state would receive a larger and closer degree of medical attention where one physician may care for either two thousand or more patients, as permitted under this scheme, than they now receive where the proportion of physicians to population is about as one is to seven hundred eighty. Moreover, your Committee is satisfied that the quality of medical attention would no more be benefited in the United States than it has in Germany, Austria, and Great Britain, by the conversion of medical practice from its present plan into an enormous scheme wherein the practitioner would be employed from year to year under contract, and in the final analysis subject to lay dictation as to means and methods of practice.

Your Committee feels very strongly that the inquisitorial powers which would be conferred upon the State Industrial Commission and its agents, and upon the local boards of directors, must be considered in its effect upon the public health, and especially as to the rôle it might assume in submerging and nullifying the activities of the present State Department of Health which has played so large a part in the reduction of morbidity and mortality by means of preventive, not palliative, medicine.

There is no uncertainty about the evidence that the relative morbidity rate, mortality rate, infant mortality rate, and maternal mortality rate, have been much more

materially reduced in the United States during the past twenty years than they have been in Germany and Austria where compulsory health insurance not alone, but the whole scheme, including invalidity and unemployment insurance and old age pensions, have been in force. It can, therefore, be seen that compulsory health insurance . . . has been of extremely little value, medically, in those countries; while it has been the cause of a profound deterioration in medical service and medical morale. Even in England, where it has been in operation for a comparatively short time, it has proved so defective and ineffective for the purposes for which it was instituted that it is now proposed to inaugurate the plan of state medicine to supplant it.

Your Committee, therefore, finds:

First.—There is no necessity for the institution of a scheme covering the major portion of the population of the state providing for the institution of contract medical practice on a colossal scale in order to furnish medical attendance and other services.

Second.—In those countries where this scheme has been in operation for many years, it has caused a deterioration in medical morale and medical service and its effect in this state would be the same, that is, a lessening in the quality of medical service.

Third.—In comparison with those countries where this scheme has been in operation the United States shows a more marked reduction in mortality rate, both general and as affecting maternal and infantile mortality rate. Apparently the morbidity rate under the scheme has doubled instead of being diminished in Germany and Austria since the institution of the social insurance plan.

Fourth.—There is danger of the scheme gradually undermining the functions so extremely valuable to the community at present subserved by the State Department of Health.

Fifth.—Owing to the paucity of accurate and unimpeachable data collected by means of an unbiased investigation, your Committee recommends that the Legislature of 1920 be requested to appropriate a sufficient sum of money for the use of the Health Department, and such other departments in association with it, as it requires, for the purpose of making a survey of the state of New York to determine the amount and character of illness in its economical relation to the commonwealth.

Sixth.—If additional legislation is to be enacted, it should provide for a greater development of existing agencies for preventive medicine, together with the extension on a large scale of the present county and municipal functions for both preventive and remedial medicine, and it should make further provision for the inauguration of more widely extended utilization of the present institutional clinical facilities for the diagnosis and treatment of disease, in order to facilitate the access of the entire population of the state to modern methods in the practice of medicine.

Your Committee, therefore, recommends that the House of Delegates, and, through them, the Medical Society of the State of New York, unqualifiedly oppose the enactment by the Legislature of the State of New York of any law instituting a system of compulsory insurance against sickness because of its menace to the public health of the state.

This report, acquiesced in by a majority of the whole Committee, is the result of a meeting held in Utica, New York, November 9, 1919, at which time twelve members of the Committee were present.

ALBERT T. LYTLE,
Secretary for the Committee.

MINORITY REPORT[1]

TO THE HOUSE OF DELEGATES OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK:—

The undersigned is unable to agree with the majority report of the Committee to study the subject of compulsory health insurance with special reference to its relationship to the medical profession.

For the sake of brevity and directness, the essential matter of the present report is presented in the form of a series of resolutions, setting forth certain guiding principles which were formulated after a careful study of the subject assigned to the Committee. In what follows, members of the Committee will recognize principles which were adopted, nearly all of them without a single dissenting vote, at a meeting of the Committee held in Brooklyn on Saturday, July 26, 1919, fifteen members of the Committee being present and voting.

(1) Unless the great mass of the population, including workers and their dependents, are brought within the scope of the proposed Health Insurance Law, no material improvement can be effected in the organization of the medical profession, nor can the benefits of medical science be more widely and satisfactorily applied than by means now available. This Committee, therefore, holds that the insurance funds must furnish surgical, medical, and nursing attendance, and the prescribed treatment, not only to insured persons, but to the dependent members of their families.

(2) Believing that the rural population now receives inadequate medical attention, we recommend that agricultural laborers be definitely included among the compulsory insured.

(3) Domestic servants should be included among the insured.

(4) No health insurance plan can be regarded as satisfactory which does not make available for the insured persons an improved grade of medical service, including the services of competent consultants and specialists; specific provision should be made for consultants, and consultant services should be organized in some form of group diagnostic clinics.

(5) Hospital maintenance should be distinguished from medical attendance in hospitals; that it, the insurance firms should not be permitted to make inclusive arrangements with hospitals for maintenance plus medical services, but hospital maintenance and medical service in hospitals should be treated as separate items.

(6) It is essential that any health insurance bill should provide for payment for professional services in proportion to the service rendered.

(7) The capitation system of payment is opposed.

(8) The employment, by funds operating under any health insurance law, of attending physicians or surgeons on salary is opposed; there should be a single system and principle of payment applicable to all insured persons, whatever the character or kind of fund in which the insured persons may happen to be insured.

(9) The health insurance bills heretofore presented to the legislature have failed to provide for such an organization of the medical profesion as would make the voice of the profession effective in negotiating rates with the funds; in the opinion of the Committee, the most promising form of organization for this purpose is one in which the whole body of legally qualified practitioners in the state would have representation and voice.

1. Owing to an error, this Minority Report was not presented to the meeting of the House of Delegates, and does not appear in the minutes of the meeting.

(10) Provision should be made for dental, nursing, and laboratory service for the insured and for the dependent members of their families.

(11) In making provision for laboratory and research work insurance funds should deal with health departments as far as possible.

(12) Free choice among all legally qualified physicians and surgeons practising in the state, should be granted to the insured.

(13) Physicians practising under any health insurance law should have the privilege of refusing to care for an insured person.

(14) Rates of compensation for medical services should be readjusted at intervals not greater than twelve months.

(15) The participation of commercial or profit making insurance companies in health insurance under any state health insurance law is opposed.

(16) Funds should provide maternity care for insured women and for the wives of insured men.

(17) Fees for obstetric services hould not be fixed by law.

(18) The use of the word "panel" to describe physicians rendering service under a health insurance law, thereby distinguishing and segregating certain practitioners or groups of practitioners is objectionable; in place of the word "panel" there should be some other appropriate designation for the group of reputable and qualified physicians who may elect to practise under the law.

(19) Except with the special consent of the State Insurance Commission, no physician in general practice should at any time undertake the care or treatment of more than 500 insured persons with the dependent members of their families, unless it can be shown that there is not a sufficient number of practitioners in the district to provide one physician for each 500 families.

(20) For the purpose of facilitating the careful and deliberate organization of medical practice under any health insurance law, a period of not less than eighteen months should be permitted to elapse between the passing of the Act and the time of its enforcement.

(21) No medical officer employed by a fund for the determination of sick benefit allowances should be permitted to practise medicine in any capacity under the law.

(22) The qualifications of the medical officers of the funds should be prescribed by the state Civil Service Commission.

(23) Two additional State Industrial Commissioners, both reputable physicians, should be appointed for the purpose of administering any health insurance law.

(24) The Board of Directors of the several funds should consist of equal numbers representing the employers and the employees, and at least one additional director who should be a physician, and who should be chosen by a majority of the directors.

(25) There should be in all districts a medical office building to serve as a center where general practitioners and the specialists engaged in the treatment of ambulatory (insured) patients can do their work; these buildings should contain the proposed diagnostic clinics.

(26) It is proper that the state contribute a fixed percentage of the total cost of administering the proposed compulsory health insurance law.

The undersigned believes that the demand for the distribution of the burdens arising from sickness cannot and should not be suppressed and that the demand for a wider application of the benefits of medical science is justified, and favors carefully considered legislation with these objects in view.

It is believed that the medical profession can perform a more valuable public service by earnestly assisting in framing a sound health insurance law than by merely opposing the enactment of proposed measures which are not satisfactory.

The adoption by the House of Delegates of the above principles, to which fifteen members of the Committee, on July 28, 1919, gave their assent, is respectfully suggested as a measure in keeping with the best traditions of the medical profession.

Respectfully submitted,

S. S. GOLDWATER, M.D.,

New York, November 16, 1919.

Appendix: Comments on Majority Report

The instructions of the Committee appointed to study the question of compulsory health insurance were "to study the subject of health insurance with special reference to its relationship to the medical profession and to report back to a special meeting of the House of Delegates." Although the majority report does not strictly confine itself to the assigned topic, it seems proper here to follow the general direction of that report.

According to the majortiy report,

The essential components of all compulsory health insurance schemes are two, *viz*:—the provision of a cash indemnity during a relatively brief period of incapacity to labor due to illness; secondly, the provision to the insured and their dependents during a determinate time of so-called medical benefits which comprise medical, dental, and nursing attendance, hospital and sanatorium accommodations, maternity attendance, drugs, and all necessary medical and surgical supplies.

"The proponents of this legislation" *i.e.*, compulsory health insurance legislation, says the majority report, "rest their demand for the institution of this scheme in America upon two main allegations: (1) that a very large amount of poverty is due to illness causing consequent unemployment and loss of income; (2) that a vast amount of the population receives inadequate and insufficient medical attendance, that is, that medical attendance is grossly deficient both as to quantity and quality.

The majority report in discussing the relation between sickness and poverty makes the sweeping statement that: "The preponderance of evidence is against the fact that any considerable amount of impoverishment is caused by illness," and refers to a single local survey in Baltimore. As to the relation of disease to poverty, in New York state, the following actual experience of organizations engaged in the relief of poverty in this state is offered in evidence:

In New York the Charity Organization Society stated in 1916 that 37 per cent of the families assisted by it were dependent because their wage earners were disabled by sickness.

The Association for Relieving the Condition of the Poor states in its report for 1918 that, "It is increasingly being realized that at the root of most necessities for relief is a health condition, or more accurately a lack of health condition."

The Buffalo Charity Organization Society reports that "sickness is more serious in our work for the poor than anything else." Numerically, it is the most important cause for relief. Relief organizations in Utica and other cities of the state duplicate this experience.

The New York State Board of Charities states in its report for 1918 that, "A study of the causes of dependency reveals the fact that much of it is due to sickness. It has been estimated that the sickness of workingmen, with the consequent expense of medical treatment and loss of pay, is responsible for more than six times the amount of dependency caused by industrial accidents. . . . A large amount of the funds contributed by private charities for the care of families in their homes

is made necessary because of sickness. Studies of charitable work have made the proportion more than 50 per cent."

The official commissions appointed to investigate health insurance which have gone into the matter most carefully have reported similiar conditions in their states after official investigation—such as the majority urges should be made in order to establish these and other facts.

The majority's statement that "illness is but a very minor cause of unemployment as compared even to the conditions of the weather or labor disputes" tells rather heavily against labor disputes and the weather, but can hardly be considered seriously as an argument against compulsory health insurance.

The argument that "where impoverishment is caused by illness, it is due to long enduring disability" may be advanced logically by those who desire more liberal insurance features than have generally been suggested by the proponents of compulsory health insurance who recommend that cash benefits should be paid for a period not greater than twenty-six weeks in any one year. Such an argument has, however, no weight against the principle of distributing the burdens that spring from illness.

The majority states in its report of November that it has been "unable to find any available evidence that will bear inspection proving that, in the main, medical attendance in this state is grossly deficient in quantity or grossly defective in quality." The majority continues,

If these facts were true, it is unable to satisfy itself that the people of this state would receive a larger and closer degree of medical attendance where one physician may care for either two thousand or more patients as permitted under the scheme than they now receive where the proportion of physicians to population is about as one is to seven hundred eighty.

But on July 26, the Committee adopted the following resolutions:

Unless the great mass of the population, including workers and their dependents, are brought within the scope of the proposed health insurance law, no material improvement can be effected in the organization of the medical profession, nor can the benefits of medical science be more widely and satisfactorily applied than by means now available. This Committee therefore holds that the insurance fund must furnish surgical, medical, and nursing attendance, and the prescribed treatment not only to insured persons but to the dependent members of their families.

Believing that the rural population now receives inadequate medical attention, we recommend that agricultural laborers be definitely included among the compulsorily insured.

In support of the inadequate medical care mentioned the second resolution of last July, the data gathered by the Committee on Social Insurance of the American Medical Association and by state authorities may be cited. This investigation found that while in the Borough of Manhattan there were 418 persons for each physician, in upstate industrial communities such as Schenectady there were 694 persons to one physician, and in centers having a population of less than 2,500 persons, despite the greater difficulty of handling large practices, there were 783 persons to each physician. The reports of the New York State Board of Charities show that of 189 dispensaries in the state, 135 are located in New York City and that over 90 per cent of the treatments given are in New York City. Hospitals show a similar concentration. Of the 186 hospitals in the state which receive public funds and which report to the State Board of Charities, 110 or 59.1 per cent, are in New York City. But of the patients treated in these hospitals, 78.1 per cent were cared for in the hospitals of New York City during nine months of 1916. Charity treatment from the dispensaries of New York City is received by approximately 20 per cent of the city's population, according to the findings of the Committee on Social Insurance of the American Medical Association. The Committee also found that 37.5 per cent of the city's physicians worked in these dispensaries, usually without remuneration. Available testimony showing the inadequacy of a large part of the work done in dispensaries, is too voluminous to be introduced here. It is an extension of this demoralizing system, necessary as it is at the present time, that the Committee recommends as an alternative to health insurance.

The proportion of physicians to population of this state is approximately one to 780, according to the majority report, and one to 640 according to statistics compiled from the Medical Directory by the Social Committee of the American Medical Association. Regardless of this discrepancy, medical service in New York state is very unevenly distributed, as the above figures indicate. Medical organizations and committees have repeatedly demanded that in any scheme of compulsory health insurance, free choice of physicians should be allowed; but again and again it has been pointed out that free choice without any limitation of number opens up the danger of concentrating a large proportion of the work to be done in the hands of so few men that the work undertaken by them will not be well done, and, furthermore, that a few aggressive practitioners might profit unduly by the opportunities created by the system. The Committee itself on July 26, adopted a resolution urging such a limitation as the majority now criticizes. Because of such objection there was introduced into the Davenport Bill a provision limiting the number of individuals who might be cared for during the year by any one physician practising under the Act, but was subsequently removed because of the opposition of the medical profession. The majority's comments on this phase of the question are most misleading, since they imply that no physician today undertakes the maximum service that might be undertaken under a former limitation in the proposed health insurance law. There are physicians today who have on their books the names of more than three times the average number of patients treated by each physician in the state. Among 2,000 insured persons, workers and dependents included, there would ordinarily at any one time be about forty persons incapacitated; but there are physicians who today see forty or more persons daily in their offices alone, and who may be responsible at any one time for the care of 200 sick, representing 4,000 of the population. With unlimited free choice of physicians under health insurance, patients would be no worse off than they are today; with free choice of physicians plus a reasonable number limitation, the patients' chance of obtaining adequate medical service obviously would be better than they are today.

The majority expresses an opinion that:

The quality of medical attention would no more be benefited in the United States than it has in Germany, Austria, and Great Britain, by the conversion of medical practice from its present plan into an enormous scheme where the practitioner would be employed from year to year under contract, and in the final analysis subject to lay dictation as to means and methods of practice

There is no reason why a compulsory health insurance law in this country should follow, so far as medical service or administrative methods are concerned, the laws of any other country. The possibility of avoiding errors into which foreign legislators have fallen, is open to us. Indeed, the precise way in which such errors can and should be avoided is indicated in the twenty-five resolutions adopted by the committee on July 26, 1919. Legis-

lation framed upon these lines would be a distinctly American product, departing radically in its medical service features, for example, from the English law. While the English law is defective from the American point of view, the testimony submitted to the Committee by Margaret Bondfield, delegate from the British Trades Union Congress to the American Federation of Labor Convention, brought out the fact that health insurance was improving the health of the British people because for the first time many could afford to take care of their health. She said that as early as 1914 an official British investigating commission found that as a result of the rest obtained under the Act, certain cases had attained better health than they had known in years.

Contrary to the statement of the majority that the British Act has proved so defective that it is proposed to inaugurate a plan of state medicine to supplant it, Miss Bondfield presented evidence to the Committee showing that in 1916 the Conference of Local Medical and Panel Committees, consisting of representatives of doctors engaged in health insurance practice, affirmed that state medical service would meet with their strongest opposition. She also stated that in 1917 the Insurance Acts Committee of the British Medical Association also reported a very general preference for an improved panel system rather than for state medical service. The Committee, moreover, recommended, said Miss Bondfield, that medical care under the Health Insurance Act be extended to include hospital care, consultant and specialist service and nursing, and that these, as well as the limited benefit provided under the original Act, be extended to the dependents of insured wage earners. This recommendation seems to have been due, Miss Bondfield pointed out, to the realization among the leaders of the profession that the alternative to such an extension was state medical service. Recent publications report conferences upon these extensions of medical benefit between the Insurance Acts Committee of the British Medical Association and the insurance authorities.

Miss Bondfield also specifically brought to the Committee's attention the following conclusion of the Insurance Acts Committee of the British Medical Association, reached after circulating questionnaires among the profession, that:

> The degree of unanimity so far disclosed is somewhat remarkable. On a subject which five years ago was the most highly controversial that had ever been before the medical profession, and which still in some places, and everywhere in some of its aspects, excites argument, it is found (1) that many matters which at the beginning of the controversy gave rise to most apprehension have assumed a position of quite minor importance; (2) that the general system by which the state provides medical advice and treatment under the insurance scheme is in the main approved, and that criticisms have a tendency to concentrate upon a comparatively few points. . . .; (3) that there is a large body of opinion in favor of the extension of the health insurance system both to kinds of treatment not at present provided for and to classes of persons at present excluded therefrom.

The statement that the majority "feels very strongly that the inquisitorial powers which would be conferred upon the State Industrial Commission and its agents, and upon the local boards of directors must be considered in its effect upon the public health, and especially as to the rôle it might assume in submerging and nullifying the activities of the present State Department of Health which has played so large a part in the reduction of morbidity and mortality by means of preventive, not palliative, medicine" can only be characterized as misleading. The majority does not undertake to show that compulsory health insurance requires "that inquisitorial powers be conferred upon the State Industrial Commission or its agents." The principal functions of the State Industrial Commission (if that body were in fact entrusted with the administration of a compulsory health insurance law, though such a law might easily be drafted without reference to the State Industrial Commission) would be to provide for the payment of cash benefits to the sick during periods of unemployment due to disability caused by sickness and to provide necessary medical care. The claim that the performance of these simple functions would "nullify the activities of the State Department of Health" is utterly unreasonable!

Moreover, the actual experience of Great Britain during seven years' operation is directly to the contrary. In a survey of the field of public health activities in Great Britain, the Ministry of Reconstruction reported in 1919 that:

> The practical administration of this novel provision immediately threw into strong relief the somewhat dehumanized characteristics of the public health system, together with the narrowness of its limitations and the inadequacy of its administrative provision. In 1914 Mr. Lloyd George pointed out that "the Insurance Act has done more than any number of Commissions to locate, to define, and to classify the problems of public health. I will not say it has revealed, but it has given prominence to one very striking fact—that an immense number of men and women, through that lack of vitality and stamina which comes from unhealthy conditions and surroundings, live lives that are a prolonged struggle against debility and disease." The attention thus drawn to these conditions not only stimulated provision for the direct alleviation of existing suffering, but also encouraged the rediscovery, as it were, following the course of evolution of medical science, of a humaner principle of prevention, as the means by which the sufferings of the individual could best be relieved or averted.
>
> In another general respect the Insurance Act entirely altered the previous position. It created a new body of organized public opinion with a financial interest in the improvement of the national health.

Summary

The evidence submitted above, which the majority has ignored, shows conclusively that sickness plays a most important rôle in compelling persons to seek charity. The Committee called attention to the inadequacy of medical care in rural districts in its July resolutions; to its inadequacy in New York City I can personally testify. To overcome existing shortcomings in medical practice, the Committee formulated and adopted last July a constructive program for the organization of medical care under health insurance. That program constitutes the substance of the present minority report.

S. S. GOLDWATER.

SUMMER CAMPS TO SUPPLEMENT PHYSICAL TRAINING

Physical training afforded to the youth of New York state by compulsory military training is inadequate according to Dr. Felix Adler of the State Reconstruction Commission, who has announced that that body will recommend establishment by the state of summer camps at which boys between sixteen and eighteen years old may spend two weeks with a program of sport for the rest of the year, supervised by the Department of Education.

"Camp life," said Doctor Adler, "gives youth community spirit, while the military training law asks the boys to bite off more than they can chew by trying to implant into their minds full grown a big thought." This, he added, engenders a "feeling of duty rather than a spirit of sacrifice."

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

A TEXT-BOOK OF UROLOGY IN MEN, WOMEN, AND CHILDREN. Including Urinary and Sexual Infections, Urethroscopy, and Cystoscopy. By Victor Cox Pedersen, M.D., F.A.C.S., Consulting Physician to Selective Service, Headquarters, New York; visiting urologist to St. Mark's Hospital, etc.*

The outstanding feature of this work consists in the author's attempt to present the entire problem of urology in a new and original manner. To quote his own words: "It is planned on a rather uniform discussion of the clinical side of the diseases included, for the benefit of students and general practitioners who, in not being widely familiar with the subjects, will be served by a fixed viewpoint."

The meaning of this exact quotation may not seem entirely clear, but this sentence, most assuredly, is a fair example of many other similar ones in this book.

Personally, the reviewer considers this new arrangement of the subject a failure. Or, to quote once more from the preface: "The disadvantage of fixed structure is a varying amount of similarity of style in passing from one disease to another or from one chapter to the next, but the effort has been made to correct this disadvantage by variations in diction." No variations in diction, sometimes clear at others obscure, help the reader to overcome his ever growing irritation of repetition, when forced to read through about three to four hundred pages devoted to the writer's eight or ten different varieties of urethritis. Each of them is singly taken up each time when pathology, symptomatology, diagnosis, etc., are discussed. This volume of urology contains eight pages devoted to gonorrheal eye infection, twelve pages on joint involvement, and refers the reader in the index to page 152 when seeking information concerning the relation of "urology" to sterility. On this page under "chronic epididymitis" appears this one sentence: "Sterility is the result of obstruction from the nodes and of destruction by the chronic suppuration." We assume, indeed, we trust that this thick volume somewhere offers some more enlightenment on this important question of sterility, but it just can not be found as the result of this new arrangement, the original feature of this new contribution to urology.

SYPHILIS AND PUBLIC HEALTH. By Edward B. Vedder, A.M., M.D., Lieutenant Colonel, Medical Corps, United States Army.†

The syphilis problem to-day is the most important health problem of this country. A thorough familiarity with this question in all its manifold aspects has become the indispensable requirement of every practitioner of medicine. He, therefore, will welcome this new enlightening contribution by a recognized expert. The small volume covers the mere statistics of the prevalence of syphilis, the various sources of infection, the problem of personal prophylaxis, including the eminently important question of marriage of the syphilitic, and concludes with an instructive discussion of public health measures to combat the disease.

BIOCHEMICAL CATALYSIS IN LIFE AND INDUSTRY. PROTEOLYTIC ENZYMES. By Jean Effront, professor in the New University and director of the Institute of Fermentations of Brussels. Translated by Samuel C. Prescott, professor of industrial microbiology, Massachusetts Institute of Technology, assisted by Charles S Venable.*

This is a translation of a work published in 1914 which was, even then, far from being up-to-date. It may be taken as an interesting and lucid account of the state of knowledge on the subjects of which it treats, as it stood about the end of 1911. Few references later than that date are found, and we noted none later than 1913. As a considerable amount of work has been done since, especially on the capital question of the actual nature of the ferments, it would have been better had the translator obtained the original author's consent to a certain amount of revision. The work is, nevertheless, of great value, especially those parts of it which deal scientifically with the industrial applications of proteolytic ferments, as in the cheese industry.

TUBERCULOSIS OF THE LYMPHATIC SYSTEM. By Walter Bradford Metcalf, M.D., associate in clinical medicine, University of Illinois, College of Medicine; member, Consulting Staff Cook County Hospital, Chicago Municipal Tuberculosis Sanitarium, Lake Geneva Sanitarium, Volunteer Medical Service Corps of the United States; formerly attending physician Cook County Hospital, Department of Tuberculosis.†

This monograph fills out a gap in the English literature on tuberculosis for, up to the present, there was no book written originally in English, dealing with the subject of tuberculosis of the lymph glands. There is one monograph in German, written by Ghon and translated into English, which deals with tuberculosis of the lymph glands. Ghon's work, however, is confined to the pathological phase of the subject, while the book of Metcalf embraces every phase of tuberculosis of the lymphatic system.

There are a number of views expressed by the author which are as yet not universally accepted. Such, for instance, is the subject of tuberculin treatment about which the author is very enthusiastic. There are many authorities on tuberculosis who believe that tuberculin is of no value in treatment. The author must be given credit, however, for his enthusiasm on the subject, and

The Day's Work and the need of Sleep

WITH a good rest and sound sleep every night, the healthy man or woman ought to feel fresh, bright, ready for anything the next morning. If you feel "tired" any considerable part of the time, it may be the fault of your *bed.* Or you may have a sturdy, noiseless bed but with a faulty *spring,* or a lumpy *mattress.*

A bed is bought to sleep in. Yet people go into store after store—inspect beds beyond number—are told everything about styles and prices, but never a word about *sleep.*

Sound sleep is a state of absolute repose—complete relaxation. The body is relaxed—digesting food, eliminating tissues used up during the day's work, rebuilding for tomorrow.

The nerves are composed—but always alert.

No matter how sound asleep you are, your nerves catch the slight rattle of your bed, the little squeak in the spring, or feel it tremble or give. They tense the muscles. And while one may not actually wake up, there is a feeling the next morning of "being all tired out."

For nearly two generations, Simmons Company have studied the needs of the sleeper and specialized in the production of "Beds Built for Sleep," that are noiseless, sturdy, comfortable; that *invite* sleep instead of repelling it.

Physicians, Public Health Officials, Nurses and Industrial Welfare Workers interested in the subject of sleep will find much that is helpful and timely in the booklet recently issued, "What the Leading Medical Journals and Health Magazines say about Separate Beds and Sound Sleep." A copy of this booklet will be mailed upon request.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber'a address should give both old and new addresses. Notice should reach us fifteen daya in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, newa items, etc.), correapondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully aolicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every inatance.

BOOKS OF THE MONTH

(Continued from Page 178)

for the manner in which he presents it to the reader. After all, it is the privilege, nay, the duty of an author to express his own views on the subject he is dealing with, and the intelligent reader of today expects a book to be not only a mere compilation of subject matter, but also a decisive expression of the author's ideas based on accumulated experience.

The reference at the end of the book is helpful, although not uniform. At times, only the year in which an article was published is given, and not the volume or the month; at other times the volume is given, but the page is omitted. Very often the volume is indicated by Roman numerals, and then again by Arabic numerals. This, however, is a mere detail, and should be overlooked in view of the enormous amount of materials contained in this valuable little book.

THE REALITIES OF MODERN SCIENCE. An Introduction for the General Reader. By John Mills, Research Laboratories, Western Electric Company, Inc.; member, American Physical Society. Author of "Radio-Communication," etc.*

The development of physical science establishes the essential unity of all natural processes. School curricula which consider physics and chemistry so separate that they are studied in different years and from texts which carefully refrain from encroaching on each other's fields are perhaps to blame for the confusion that exists in the average conception of scientific relationships. All who feel the need of a better orientation in modern science will find this book by Mr. Mills of distinct service. It gives an interesting account of the historical development of the fundamental concepts of science and makes an easily comprehensible statement of quantitative relationships. It should appeal to the average well informed reader as well as to the physician.

The realities of modern science he states to be matter, indestructible and irreducible; and energy, exactly measurable and subject to transformation, but not to loss. In chapters on the motions and interactions of electrons, the continuity and correspondence of molecular states, electrolytic dissociation, molecular magnitude, and molecular energy, he discusses the electronic constitution of matter which today is commonly accepted. "Its development has been so rapid that few scientists besides those actively engaged in research have as yet adopted its terminology and the necessary point of view. In terms, however, of electrons and quanta, the scientific progress of the next few years will undoubtedly be expressed."

THE LIFE OF MATTER. By Arthur Turnbull, M.A., B.Sc., M.B., (Glasgow).†

As stated in the introduction, the work purports to supply a reliable guide and insight into observational method and experiment, and to afford an interpretation of the application of modern science to the necessities of life. Part I treats matter as dead and inert, the elements apparently unrelated until the substances were arranged in such sequence as to enable the prediction of the existence of elements not then discovered; but even his first chapter hints of behavior in certain elements for which adequate explanation has not been offered.

A rapid sketch follows of matter in action; of opposite action, from cloud to star, from element to plant and

INFLUENZA

DICHLORAMINE-T

Will Tend to Prevent Influenza

During the influenza scourge of the fall and winter, 1918-1919, Dichloramine-T received careful trial by many prominent practitioners. These men believed that since Dichloramine-T had proven its power to protect against diphtheria, meningitis, and similar infections originating in the upper respiratory tract, it should have the same power against influenza.

Thousands of people, in some cases the entire working force of large industrial plants, received sprays, twice daily, to the nose and throat, of a 2% solution of Dichloramine-T in Chlorcosane.

Results fully justified their faith. Wherever the Dichloramine-T sprays were used regularly, influenza failed to become epidemic. The power of Dichloramine-T to prevent influenza was fully tested.

Let's Be Prepared

At the first indication of a return of the influenza epidemic, resort immediately to this tested line of defense. Meet the enemy at port of entry, rendering the upper air passages hostile to his development and you've won the battle. Prescribe and use Dichloramine-T in Chlorcosane, Abbott.

Literature on Request

IN THESE PACKAGES:

DICHLORAMINE-T
Powder in 1 oz. bottles and 4 oz. bottles.

CHLORCOSANE
In 4 oz., 16 oz., and half-gallon bottles.
CHLORCOSANE Atomizer, $1.25

CHLORAZENE

AS a Gargle

Chlorazene, Dakin's water soluble antiseptic, is used in 0.25 per cent solution as a gargle every two hours following the Dichloramine-T spray, to enhance the effect. It is also recommended as a gargle before boarding street cars, trains, or entering other public places. It keeps the throat sweet and clean and aids in preventing the breeding of harmful bacteria.

For Influenza Prophylaxis *Spray with DICHLORAMINE-T twice daily to nose and throat*
GARGLE WITH CHLORAZENE 0.25 solution every two hours

Supplied in the following packages:
Chlorazene Tablets, 4.6 gr. each. Bottles of 100, 500, 1,000. Chlorazene Powder, Pkg. No. 1 makes 4 gallons 0.25 solution. Pkg. No. 2 makes 20 gallons 0.25 solution. Also Chlorazene Surgical Cream and Chlorazene Surgical Powder.

BOOKS OF THE MONTH

(Continued from Page 22)

animal tissue; natural selection in the development of species; adaptability; external influences; and the nature of force or energy. Again in the chain of forces he finds the usually ascribed causes incomplete, but all sufficiently indicating that all the changes in nature have something in common. "Force flits, a ghostly body, from one piece of dead matter to another, activating them in turn, as a bee flits from flower to flower, fertilizing them as it goes."

He rapidly traces the development of man, the decisive factor in every change being the previous condition of the thing changing. He is not satisfied to accept Weisman's theory of man as the more or less passive medium of the current of life passing from one generation to another. He discusses so-called "free action" as proceeding from the brain memory of past sense impressions. In passing, he comments on "body and germ," the danger of disease corroding the finer paths of the brain, and of the unintelligent waste of money and effort in the endeavor to "train out predetermined effects of bad hereditary determinants."

All of which leads up to his discussion of the need for inquiry. The natural selection of Darwin, he says, fails to explain the differences of tissue, does not account for the decline in the fertility of a race or for many forms of degeneration. He proceeds to develop his thesis of energy stored and energy transformed. Change is never from without; an external cause is never a controlling factor, and the end difference or result depends upon the internal cause and inner strain. All hitherto unexplained phenomena he attributes to universal life processes, or "activation."

His "action-strain-result" leads him to regard minerals, plants, animals, and man as "active." This constitutes for him a basis from which to reason out the nature of changes which cannot be expressed in the finite terms of our modern science and he evolves the aphorism that "activity is too simple to be understood. . . . (1) Every form of matter is active and eternal. (2) Like causes never produce like effects. Every action is different. Every change is new. (3) Action and reaction are unequal. There is no such thing as a reflex. . . . No individual is merely a more or less complex tissue-unit." He deduces that the life of mankind has a higher value than it has hitherto attained.

DISEASES OF INFANTS AND CHILDREN. By Henry Dwight Chapin, A.M., M.D., professor of diseases of children, New York Post-Graduate School and Hospital; Supervising Physician of the Children's Department, New York Post-Graduate Hospital; Consulting Physician to the Willard Parker Hospital, etc.; and Godfrey Roger Pisek, M.D., Sc.D., professor of diseases of children and attending physician to the New York Post-Graduate Medical School and Hospital; professor of diseases of children, University of Vermont, Medical College; Visiting Physician to the Willard Parker and Riverside Hospitals, etc.*

The present is the fourth edition of this work, the first appearing in 1909. Many of the chapters have been revised, and new subject matter added in the form of chapters on Acidosis, Food Allergy, Epidemic Encephalitis, Functional Heart Disorders and certain phases of spasmophilia.

It would seem as though the revision to which the work was subjected before the appearance of the present edition might, with much profit, have been made more thor-

FOR DIET CONTROL IN INFANT FEEDING

The choice of these dependable products affords the physician convenient means of selecting food mixtures suited to the individual requirements of individual cases.

MEAD'S DEXTRI-MALTOSE NO. 1

(With Sodium Chloride 2%)

For general use in infant feeding. Especially indicated in infants recovering from diarrhoea, infants with feeble powers of digestion who have tendencies to diarrhoea. Valuable as an addition to Protein Milk.

MEAD'S DRY MALT SOUP STOCK

For difficult feeding cases. Indicated in marasmus, weight disturbance (failure to gain), infants afflicted with recurrent diarrhoea from intestinal indigestion, and those cases occasionally met which do not do well on milk, water and sugar mixtures.

MEAD'S DEXTRI-MALTOSE NO. 3

(With Potassium Carbonate 2%)

For use in constipation, when boiled feedings are used, or where the addition of potassium to the infant's diet is indicated.

Full information regarding these products furnished on request.

MEAD JOHNSON & CO. **Evansville, Ind.**

Flavor Is the Basis of All Food

Experienced dietitians recognize Flavoring Extracts as first aids to convalescence—making nourishing foods and drinks more palatable, hence promoting digestion and assimilation.

Since, in the feeding of the sick and convalescent, flavor is such an important factor, it follows that physicians and dietitians should insist on the use of only the purest and strongest flavors. The best is always the most economical when the insignicant cost per pound of food flavored is considered.

SAUER'S
PURE FLAVORING EXTRACTS

are made from the choicest materials obtainable in a modern and sanitary plant with every possible care taken in their manufacture. Prepared in glass lined tanks and filled by vacuum into sterilized bottles.

Sauer's Extracts have won seventeen highest awards and medals at various American and European Expositions for

Purity, Strength and Fine Flavor

Uniform high quality has made Sauer's the largest selling brand in the United States.

ough. For instance laryngismus stridulus is described on p. 350,. spasmophilia on p. 481, and tetany on p. 483, each under its own separate heading, with separate (and different) "etiology" and "treatment." The importance of the role played by the calcium salts in the metabolism is not emphasized, and no mention made of the brilliant results of treatment with magnesium sulphate when given hypodermically. Similarly, in discussing hydrocephalus, the only factors mentioned as having a possible etiologic bearing are "parental alcoholism, tuberculosis, syphilis and neurotic diseases" but not a word about the splendid studies of Dandy and Blackfan which not only place the pathology of this condition on a firm foundation but in certain instances even point the way to successful treatment. Again, under "keratitis" phylctenules are described as vesicles when in reality they are not vesicles but solid nodules.

The book contains some good tables on growth, development and the composition of many so-called infant foods, as well as some very helpful diet lists for older children.

THE PHILOSOPHY OF CONFLICT and other essays in war-time. By Havelock Ellis.*

This delightful collection of essays treats many diverse topics, but through them all runs a thread of continuity as they constitute a many sided view of the problems of reconstruction to be solved after the war. The things he sees do not altogether please him, but he sounds a warning against admitting only the facts which it is pleasing to believe.

Through the rise and fall of successive civilizations he traces the kinship of the warring peoples. The result of any conflict must serve concrete biological ends. An enemy, he says, can inflict on us no such defeat as we have power to inflict on ourselves by falling to any lower level. "Let us not, therefore, lose sight of the difference between the great ideas which carry men forward and the violences and extravagances which carry men back, for . . . it is the men who look forward who live." He considers that war itself must eventually disappear. War has served its purpose. Without struggle and conflict there would have been no world at all. Conflict, contact, interaction of different cultures have furnished "the starting points of all the great movements in human history which we are accustomed to regard as progressive."

The two causes of war are already decaying, he says. The birth rate necessarily falls with every rise of culture. Likewise, excessive industrialism has passed its climax. There is no more world left to fight for. With the regularization of industrial and commercial activities, the economic cause of war falls away, and the energy thus released is free for sublimation into more exalted forms of activity.

Perhaps the most significant chapters are those devoted to the eugenic policy of the future. The military idea that a high birth rate means military efficiency is altogether fallacious. The European countries with the highest birth rates are precisely those which have met overwhelming disaster in the war. Intelligence, initiative, resourcefulness, endurance, caution, courage, the discipline that causes self-reliance and mutual reliance,—all the fundamental human qualities can only be developed slowly by free activity in the manifold business of ordinary life.

An Important Food Discovery

HEBE—a wholesome, pure, economical food

PHYSICIANS, hospital executives, and health officials—those most concerned with the health and welfare of the nation—should be interested in the new food product, HEBE, not only because of its dietetic value, but also because of its importance as an economic addition to the world's food supply.

HEBE is a scientific emulsion of evaporated skimmed milk and cocoanut fat. HEBE reclaims for human use skimmed milk which is otherwise so largely diverted to stock-feeding, and puts it in form to make its use desirable as a cooking ingredient. This releases for direct feeding purposes a large volume of the whole milk now used in cooking and increases the use of dairy products in the home.

It is known to all students of food values that skimmed milk lacks only the butter fat to make it a perfect human food. With the addition of pure, scientifically processed vegetable fat, skimmed milk can be made an easily digestible, nutritious food. Thus enriched, it makes a desirable, economical and healthful ingredient in cooking and baking, and can be used in coffee, too.

HEBE is a wholesome food, rich in necessary dietary elements—proteins, carbohydrates and fat. In every one hundred pounds of HEBE there is all the food value of 210 pounds of skimmed milk *plus* the heat and energy value of 7.8 pounds of pure, refined vegetable fat. In the reduction, water only is removed.

HEBE is all that a good food should be. The high nutritive value and absolute purity of the ingredients, the scientific processing in manufacture, and the extreme sanitation observed in the production and marketing of Hebe should secure for it the most hearty approval.

In these days of food shortage and high prices the production of a new food possessing the advantages of Hebe is an event of interest to health authorities, physicians and food chemists. We will gladly send, upon request, a booklet giving the complete facts about the dietetic and economic value of HEBE. Address 2222 Consumers Bldg., Chicago.

Electrically Lighted Surgical Instruments

The Sign of Service

E. S. I. Co.

Ours is a name of accomplishment in the cause of diagnosis. In the beginning an electrically lighted surgical instrument is made to embody the ideas of a distinguished physician or surgeon. Each accomplishment by the light of this instrument is a tribute to his skill and its efficiency, opening the way to greater gains for diagnosis and to suggestions for betterments in instrument construction.

Building upon the ideas and from the suggestions of these physicians and surgeons, admittedly great in the respective branches of their exacting profession, is the story of "E. S. I. Co.," from the origination of electrically lighted surgical instruments up to the indispensable service they render today.

Origination begets imitation. Be sure of our name.

BOOKS OF THE MONTH

(Continued from Page 26)

The old problems of eugenics have acquired a new urgency for preventing the breeding of the unfit, for dealing with the actual and threatened spread of venereal diseases, and for enlarging and requickening sexual morality and social customs in such a way that women may be permitted free play of their best impulses and ideals in the purification and fortification of the race of the future. He emphasizes the fact that we possess in birth control an invaluable instrument for immediate social betterment and for the elevation of the race. He gives serious consideration to the problems involved and says that work can progress in three directions toward rendering eugenic ideals effective, (1) by increasing and promoting knowledge of the laws of heredity; (2) by popularizing a knowledge of the methods of birth control; and (3) by acting in accordance with our knowledge. This last does not involve hasty eugenic legislation so much as sifting out the "irreducible nucleus of the incapable group which constitutes a real anti-social danger and a focus of racial poisons."

Succeeding chapters deal with war and the sex problems, the unmarried mother, with the social and economic status of woman and psycho-analysis of sex, all as problems of social reorganization made more acute because of the war.

THE BIOLOGY OF BLOOD-CELLS. With a Glossary of Hematological Terms. For the use of Practitioners of Medicine. By O. C. Gruner, M.D., Lond. Author of "Studies in Puncture-Fluids," "A Code System for the Hospital Pathologist"; pathologist to the Royal Victoria Hospital and to the Maternity Hospital, Montreal; assistant professor of pathology, McGill University, Montreal, late clinical pathologist, General Infirmary at Leeds.*

The author starts out with a highly poetical introduction, which reads very pleasantly. To quote:

"Let the reader imagine himself to be transported by magical means to the center of an absolutely new city, inhabited by beings of a different and hitherto unknown race. How would he proceed to find out the story of these beings? He would not be content to stand at the street corner or in the gateway, and collect together five hundred of the bustling, active, hurrying toilers as they passed, and, mingling them with a few of the indolent loungers in the vicinity, proceed to classify all these persons into percentages according to their types. From a convenient vantage ground he would carefully note the peculiarities of each passer-by, dividing them into as many different types as he could; and he would not confine himself to a short period of the day, but would observe the different features about the people—at this time, at that; tomorrow; a month hence; by day; by night. Furthermore, it is not to be conceived for an instant but that he would look at the buildings, the roads, the material transported along the streets, and that he would feel a desire to ascertain the processes at work within those buildings; to see the factories; to see where the people came from; where they went; how they died; why they died; and what part each played in the whole fabric of life.

"It is evident, therefore, that a clear idea of the blood cells predicates more data than are supplied by taking a single drop of blood, drying it, and subjecting it to a microscopic examination. Maybe this is the only feasible procedure in a patient, but it is not the only method by which the subject can be studied."

Whooping-Cough
and
Vaccine Treatment

OSLER, HARE, FORCHHEIMER and other medical authorities agree that whooping-cough causes more deaths under one year of age than any other infectious disease. In America more than 10,000 children die each year from whooping-cough.

CLINICAL EVIDENCE indicates that Pertussis Vaccine is of value both for the prevention and treatment of whooping-cough. The average duration of the disease under vaccine treatment is about 3½ weeks as compared to 9 to 10 weeks under drug treatment. The most recent report is by Bloom (Archives of Pediatrics, January, 1919), who concludes:

1. Vaccine therapy in pertussis is rational and effective.
2. Experience has proven its efficiency both as a prophylactic and as an active therapeutic agent.
3. Usage:
   - (a) Minimizes loss in weight.
   - (b) Reduces duration of the disease.
   - (c) Decreased the intensity of the illness.
   - (d) Foreshadows possibilities of complications and sequelae.
   - (e) Unattended by danger of anaphylaxis.
   - (f) Limits the mortality.

Puffed Wheat

In Actual Size

Every Food Cell Exploded

Puffed wheat is whole wheat puffed to bubbles, eight times normal size.

The grains are sealed in guns. The guns are revolved for one hour in 550 degrees of heat. The moisture in each food cell is thus changed to steam.

Then the guns are shot and the steam explodes. Over 100 million explosions occur in every kernel. Thus every granule of the whole wheat is fitted to digest.

All Puffed Grains are puffed in like way—by Prof. Anderson's process. The result is most enticing foods, thin, flavory, flimsy morsels. And the best-cooked grain foods in existence.

They are always delightful, and in many conditions you'll consider them important.

BOOKS OF THE MONTH

(Continued from Page 28)

And again he says:

"We shall thus find that each 'blood-disease,' at some stage in its course, is the outward evidence to us of a tragedy in the life-history of the particular portion of the hematopoietic system, and we shall dimly appreciate the fact that orderly blood formation demands constant single-hearted coöperation on the part of the other tissues of the body as well as coöperation with the brain, which should see that deleterious agents are not admitted by carelessness in diet and general hygiene. Withdraw such influences, and the formative blood cells are stranded; they make desperate attempts to breed true and follow up definite harmoniously apportioned (methodized) sequences of differentiation; fail, and are irretrievably lost, because destroyed by the harmful agent, or merely maimed until such time as better conditions prevail. The individuals of the army which fight such incessant warfare under these conditions are at the same time inconstant as entities; they are ever changing, ever moving about and ever reproducing, not working together for individual purposes, but all subserving common necessities, while each still acts for himself where nutrition is concerned."

The poetry, however, disappears as soon as the text is approached, and a technical discussion, at times even too technical for the ordinary reader, takes its place.

The author shows a thorough knowledge of his subject. He has put forth a good book for biologists and technicians. We do not, however, agree with him that the book is for the practitioner of medicine. We believe it is too technical for the average practitioner.

However, if a physician wants to enlighten himself on the deeper problems of hematology in all its phases, we would strongly recommend this highly scientific book.

PULMONARY TUBERCULOSIS. By Maurice Fishberg, M.D., clinical professor of medicine, New York University and Bellevue Hospital Medical College; attending physician, Montefiore Home and Hospital for Chronic Diseases, New York.*

This is the second edition of a very excellent work on pulmonary tuberculosis. The author has a clear conception of his subject and a breadth of view which have enabled him to consider the wide ramifications of this disease most ably. The many differences in symptomatology between tuberculosis in childhood and in later life, and its peculiarities during the period of infancy, are well stated. This fact is worthy of emphasis because the relationship between infection with the tubercle bacillus during the period of childhood and the appearance of symptoms of phthisis in later life is not generally enough recognized. There are many excellent illustrations, the reproductions of roentgenograms covering almost all varieties of lesions. In discussing treatment, the author has gone into the subject of the home care of the consumptive in great detail, being perhaps a little unfair in his attitude toward sanatoriums; but since most of these patients never enter a sanatorium, and even those who do must be cared for in the home before entering and after leaving such institutions, this phase of treatment assumes an added importance.

The book has been thoroughly revised and brought up to date, and contains innumerable references to the literature, so arranged as to make them easily accessible to the reader.

STERLING
Therapeutic Lamp
"The Light That Heals"

Has proved one of the most efficient methods of relieving pain; its effect is soothing and analgesic; its rays are germicidal. The warm, soothing, soft rays penetrate and vitalize every cell and tissue, new cell growth is stimulated; the body is refreshed and vitalized.

In rheumatism, neuralgia, neuritis, lumbago, in nervous conditions and a score of other symptoms and diseases, including skin and scalp disease, the Sterling Therapeutic Lamp is invaluable for the relief from pain, inflammation and for corrective purposes.

Scientific—Efficient—Economical

With stand it is ideally adapted for additional use as a spot light for operations and examinations as illustrated. Widely used in sanitariums, physicians' offices and hospitals; special sizes are adapted for the use of patients under the supervision and direction of the family physician.

Write for our interesting Illustrated Booklet showing the various sizes and uses of the Sterling Therapeutic Lamp.

Keep Your Patient On the Job

by relieving pain and speeding recovery through the use of

Thermolite
LIGHT AND HEAT INFUSER

The industrial clinic or hospital equipped with this scientifically designed therapeutic lamp can quickly relieve many conditions which otherwise would make absenteeism imperative.

Radiant Light and Heat

delivered in *parallel* rays have deep penetration and bring quick relief from pain, reduce inflammation and promote healing.

Thermolite can be attached to any electric light socket and it will act quicker and better than drugs or local applications in

Neuralgia	Rheumatism	Chronic Ulcers
Sprains	Neuritis	Local Infections
Lumbago	Arthritis	Dysmenorrhea

and many other conditions encountered daily by the industrial physician.

Thermolite is supplied in two forms—the **Triplex** for hospital clinics and office use, and **Simplex** (single lamp with or without stand) for home use.

Value of Typhoid Prophylaxis

In a report issued by Surgeon General Ireland it is stated that the immense value of typhoid prophylaxis was very clearly demonstrated during World War. During 1917-1918 there were 1,083 cases of typhoid and 158 deaths therefrom in the Army. Had the admission rate for this period equaled that of 1861-62 in Civil War, there would have been 226,001 cases and 62,694 deaths, and, had rates been same as for 1898-99 in Spanish War, there would have been 291,637 cases and 30,916 deaths.

RECENT INCREASE IN CHILD LABOR

The Department of Labor has issued a recent report on investigations made in the summer of 1918, which shows that an appreciable increase is to be noted in violations of the state laws controlling child labor since declaration by the Supreme Court of the unconstitutionality of the Child Labor Law. Forty-seven out of fifty-three factories inspected in one state were employing children under the age of twelve, and in another state where the minimum age for employment in canneries was fourteen years, 721 children under that age were found at work, fifty of whom were under ten years old.

CONFERENCE ON PUBLIC HEALTH AND LEGISLATION

The Annual Conference on Public Health and Legislation called by the Council on Health and Public Instruction of the American Medical Association will be held in Chicago, March 4, 1920, with headquarters at the Auditorium Hotel. An all-day program has been scheduled as follows:

Chairman's Address, Dr. Victor C. Vaughan, chairman, Council on Health and Public Instruction, American Medical Association.

Secretary's Report, Dr. Frederick R. Green, secretary, Council on Health and Public Instruction, American Medical Association.

"Standardization of Public Health Activities," Dr. George E. Vincent, president, Rockefeller Foundation.

"Standardization of State Public Health Organizations," Dr. Charles V. Chapin, commissioner of health, Providence, R. I.

"Standardization of Municipal Health Organization," Dr. Allen McLaughlin, Assistant Surgeon General, United States Public Health Service.

General Discussion, opened by Dr. C. St. Clair Drake, commissioner of health, Springfield, Ill., and Dr. Ennion Williams, commissioner of health, Richmond, Va.

Symposium on Health Education of the Public

"Health Education in the Public Schools—Thirty Years' Experience in Michigan," Dr. Victor C. Vaughan, Ann Arbor, Mich.

"Health Education and Activities in Colleges and Universities," Dr. John Sundwall, director, Students' Health Service, University of Minnesota, Minneapolis, Minn.

"Health Education a Function of Municipal Health Departments," Dr. Haven Emerson, New York.

"Health Education a Function of State Health Departments," Dr. W. S. Rankin, secretary, State Board of Health, Raleigh, N. C.

"Health Education a Function of the Federal Government," Dr. Charles V. Bolduan, director, Division of Public Health Education, U. S. Public Health Service.

General Discussion, opened by Dr. John M. Dodson, Chicago; Prof. W. B. Owen.

The nutrient value of VIROL illustrated in a series of cases, particulars of which have been supplied by medical men.

CASE No. 3

Virol is valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars:
50c, $1.00 and $2.00

A photo taken three months after the one below. He had been given one teaspoonful of VIROL three times a day, with milk diet. Improvement was immediate and marked, with speedy and continuous addition of weight. Ten weeks after the above was taken the child weighed 29 lbs.

A history of wasting and severe arthritis, extending over six months. So emaciated his weight had fallen to 28 lbs. Anaemic; alternate constipation and diarrhoea.

MALNUTRITION—VIROL is a dependable nutrient and reconstructive in all wasting conditions, in tuberculosis, anaemia, gastric ulcer, rickets, scurvy and all strumous conditions.

The animal fat in VIROL is so minutely divided that it is more readily absorbed than milk. The nitrogenous elements are in a form as near digestive perfection as science at present permits.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex *to be* and *to do* and *hold her to this inspiration* by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Susanna Cocroft

624 Michigan Boulevard Chicago

CHICAGO TO REBUILD SLUMS

The rehabilitation of Chicago's slums and the rebuilding of the city's run down residences into comfortable quarters for workers, will be the program of the $1,500,000 Civic Real Estate Improvement Association, organized and backed by the Association of Commerce and the Chicago Real Estate Board. Actual building work will begin before spring. The Chicago Title and Trust Company has set aside $500,000, to be loaned on the properties of the corporation.

CORRECTION

It is to be noted that through error the captions on the illustrations of the articles of Maurice B. Hexter, appearing in the October issue of MODERN MEDICINE are not properly accredited. The Frauen Verein Home of Boston is not a constituent member of the Federated Jewish Charities; and the Convalescent Home of the United Jewish Charities is at Cincinnati, O., and not Cleveland.

ULTRA-VIOLET RAYS IN WATER PURIFICATION

The interest of persons concerned with water purification in the sterilization of water by the use of ultra-violet rays has called for a summarization of the literature on the subject which is published in *Public Health Reports* of December 12, 1919.

While different germs show different sensitivity to ultra-violet rays, all are destroyed on short exposures, according to Von Recklinghausen.[1] Water as it comes from a modern mechanical filter may be considered perfectly clear to the action of the rays. Such water may be treated at a total cost of $0.60 per million gallons. Chemical treatment may be somewhat cheaper, considering the expert attention required, but the increased cost is offset by a cleaner, chemical-free H_2O. Typhoid records from certain European towns show a total absence of this disease since ultra-violet sterilization was introduced.

The dependency of the germicidal efficiency of ultra-violet rays upon their wave length is considered in detail in a report[2] from Ontario, Can., and irregularities attending water supplies handled directly without preliminary filtration are noted. Over-dosing gives no detrimental effects aside from added cost.

A report of this method for circulating systems and small installations comes from the laboratory[3] of the Sanitary District of the Great Lakes with a very complete discussion of the method and its history.

Certain deficiencies of various apparatus are pointed out by L. Schwarz and J. Gasbel Aumann.[4] The 320 plants installed or approaching completion in the United States comprise twenty for swimming pools. For this purpose direct current is used at 110 to 500 volts in connection with a pressure filter. Sterilization is accomplished[5] at a cost of about $750 per 1,000 gallons per hour for machines of 200 to 3,000 gallons capacity, with a higher cost for machines of smaller capacity.

The bactericidal action of ultra-violet rays is uninfluenced by the temperature and oxygen content of the water, according to DeVoogt,[6] and different bacteria require different amounts of light.

Overton and Denno's

The Health Officer

By Frank Overton, M. D., D. P. H., Sanitary Supervisor, New York State Department of Health; and Willard J. Denno, M. D., D. P. H., Medical Director, Standard Oil Company. Octavo of 500 pages, illustrated. Price, $4.50, postpaid.

This new book, published in 1919, contains the information the average Health Officer must have in order to discharge his duties. It tells him what to do, how to do it, and why he should do it. It describes the various activities in which a Health Officer engages; his relation to boards of health, physicians, social agencies, and the public; his qualifications and methods of work; the various diseases and insanitary conditions with which he deals, and the scientific principles upon which preventive medicine is founded. The work is the result of ten years' experience in this field. While the book is designed primarily for Health Officers, it has a decided value to public health nurses, members of boards of health, social workers, teachers, and all others interested in organized health work.

The Modern Hospital Publishing Co., Inc.

58 E. WASHINGTON ST., CHICAGO.

CARE OF POLIOMYELITIS CASES

A survey being conducted by the New York Committee on the After-Care of Infant Paralysis Cases indicates the importance of compiling complete records of cripples and of providing adequate clinical facilities with increased means of transportation so as to bring those in need of assistance in touch with the proper orthopedic care. During the year just ended, the report shows that the Committee has taken care of 8,253 cases.

ADEQUATE CARE THE MOTHER'S RIGHT

The efficacy of the health propaganda of the United States Public Health Service depends, of course, upon educational material reaching the persons directly interested. This contact is assured by the distribution through the American Red Cross of the health bulletins "Motherhood,'" "Breast Feeding for Babies," and "Bottle Feeding for Babies." These booklets state in concise and simple form the essentials of care that make for the safety, comfort, and happiness of mother and child.

AN ORTHOPEDIC HOSPITAL-SCHOOL FOR LOS ANGELES

The Los Angeles Orthopedic Foundation, composed of seventeen prominent men in Los Angeles, with George Dryer as president, W. E. Tussing, vice-president, and H. H. Baskerville, secretary and treasurer, will provide a permanent institution to take care of the physical, educational, and vocational needs of crippled children, according to the *California State Journal of Medicine*. It will be fully equipped for corrective care, and for training the children to become self-supporting. Model cottages will be added later for the teaching of domestic science and the care of the home.

THE PHILIPPINE HEALTH ALMANAC

A health talk every day in the year is furnished by the unique health almanac published by the Philippine Health and Sanitary Service. Ten precepts for disease prevention introduce the subjects of common diseases and their remedies. There are pictorial preachments against the most common and the most flagrant bad practices, and specific help is offered on every page. From the opening page to the final pictures of sanitary model houses and gardens the book exemplifies a consistent educational health effort.

AMERICAN JOURNAL OF PUBLIC HEALTH

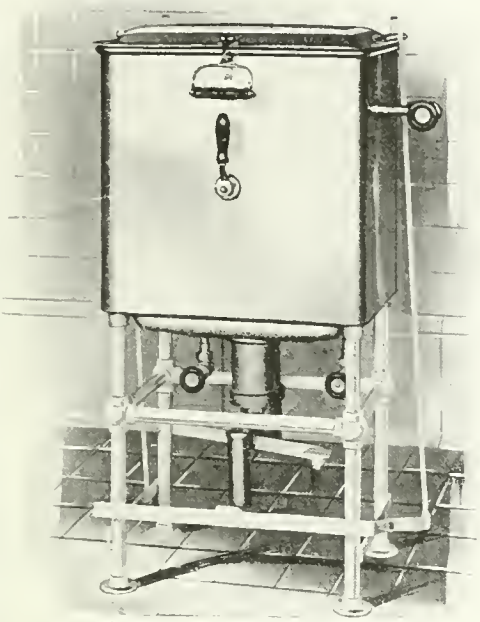
Sanitary history does not record the success of a single one of the many attempts to control by "general measures" an epidemic disease regarding which specific knowledge is not available, says Allen W. Freeman, M.D., state commissioner of health, Columbus, O., in a discussion of administrative measures against influenza, in the December issue of the *American Journal of Public Health*.

The papers read at New Orleans by Arthur Newsholme, M.D., K.C.B., on the "Historical Development of Public Health in England"; by L. L. Lumsden, M.D., on "Public Health Perspective"; by William H. Peters, M.D., on the "American Red Cross Crusade." "After Effects of Influenza in Cincinnati"; by D. B. Armstrong, M.D., on "Influenza Observations in Framingham, Mass."; and by J. W. Scherewsky, M.D., on "Needs and Methods of Coordinating Various Health Agencies in the Promotion of Industrial Hygiene," constitute a symposium on the most outstanding features of present health work.

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT



Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it. Investigate "AMERICAN" sterilizers and you will find that the secret of their success is HIGHEST QUALITY and LONGEST SERVICE.

CHECK DISTRIBUTION OF NOSTRUMS

The city of Sacramento, Calif., has taken a step forward in a regulation which is calculated to prevent the free distribution of "remedies, nostrums, or proprietary medicines." They hope thereby to prevent self-medication on the part of the people and to make it impossible for drugs of this character to reach the hands of children.

CANADA PROVIDES FOR DISABLED SOLDIERS

The Dominion Government has paid out more than $150,000,000 in gratuities, has spent $57,000,000 for re-establishment of disabled soldiers, and will spend $50,000,000 more in putting disabled soldiers in positions where they can earn a living, according to a recent statement by G. E. Foster, Canadian Minister of Trade and Commerce.

COMMISSION FOR STUDY OF INFLUENZA

The Metropolitan Life Insurance Company has provided funds for the investigation of influenza. Work is already under way in Washington, New York, Boston, and Chicago. Investigation will be made into the prophylactic value of vaccines, and laboratory researches will attempt to discover the causes of such infection and the mode of transmission. The Commission appointed for this work consists of: G. W. McCoy, director of the hygienic laboratory, United States Health Service; Dr. W. H. Park, director of the research laboratory, New York City Department of Health; Dr. Lee K. Frankel, third vice-president of the Metropolitan Life Insurance Company; Dr. M. J. Rosenau, chairman, professor of preventive medicine and hygiene, Harvard Medical School; Prof. E. O. Jordan, of the University of Chicago; and Dr. W. H. Frost, of the United States Public Health Service.

PRECAUTIONS AGAINST LEAD POISONING

A survey with particular view to determining the extent of lead poisoning in potteries has just been concluded by the Office of Industrial Hygiene and Medicine of the United States Public Health Service, and their report as to the precautionary measures against the lead hazard in this industry is published in the December 19, 1919, issue of *Public Health Reports*.

The symptoms of lead poisoning are given, as are the common parts of entry in this industry. Workers are warned to eat before going to work, to drink milk between meals, and to drink only from covered vessels. Respirators are advised for dusty places, and prophylactic care as to workroom clothes. Directions are very explicit as to personal hygiene and ventilation. In its last analysis safety measures are chiefly for the advantage of the workmen and depend for their efficiency upon his strict personal adherence to the advice given.

NOTES AND COMMENT

SPRING CONVENTIONS

FOUR conventions which will specially appeal to physicians, nurses, and social workers will be held in April in the South and Middle West. These five conventions combine more than a score of affiliated organizations which will meet at the same time and place.

The series includes the Conference of Social Work at New Orleans, April 14 to 21. The Health Section of the National Conference is always of high grade.

The Biennial Convention of the National Organization for Public Health Nursing will meet in Atlanta, April 12 to 17. The largely attended conferences of this association are assuming unusual importance with the tremendous growth of the profession.

The National Tuberculosis Association will hold its annual meeting in St. Louis, April 22 to 24. The enlarged program of this association will attract the interest of all of those attending this series of conventions.

The American Medical Association and allied associations meet in New Orleans, April 26 to 30. The greatly broadened and intensified public interest in medical matters this year has evolved issues of vital interest to the medical profession. The sectional programs are of unusual value. A large attendance at this meeting and a general participation in its deliberations by all members of these associations are urged.

The wide range of the affiliated organizations which are participating in these annual meets makes these conventions of real value to social workers as well as physicians.

PREJUDICE AND IGNORANCE

THREE news items of significant interest have come to the desk of the editor within a few days indicating that the battle of preventive medicine against ignorance and stupidity, which foster disease, is not yet completely won.

These items come from a wide geographical range. One announces the fact that a health officer in Delaware was forcibly carried out of a town and told to stay out, for doing nothing more than the promotion of sanitary and health measures. The second comes from Dallas, Tex., where an organization has been formed called the Public School Protective League to oppose vaccination against smallpox. The third comes from Springfield, Ill., where there has been introduced in the Constitutional Convention of the State a resolution guaranteeing freedom of medical practice.

If these incidents had been reported half a century ago they would have been passed by without comment, because of the common ignorance of the benefits of sanitary measures, vaccination, and regulated medical practice, but what can we say of the year 1920 when intelligent communities make an organized effort to oppose the most accepted of the doctrines of good health?

It appears that the incident in Delaware was backed by a large part of the population. The health officer himself was a capable and efficient official. Apparently he was too capable and efficient for the slow-going residents of that community. He was escorted unceremoniously from the town by a procession of automobiles filled with resident "witch-burners."

The second incident might be passed over as one of the sporadic efforts of the anti-vaccinationists except for the fact that the meeting appeared to have a considerable attendance and that proposals were made for a State and National Organization to stand, as the meeting declared, for "freedom of choice of medical treatment." It appears at the time the city of Dallas was experiencing something of an epidemic of smallpox and that the city Board of Education required vaccination. Much of the discussion, as reported in the press, appeared to be unworthy of comment, but the fact remains that a protest meeting against vaccination in the year 1920 was largely attended in a progressive city.

The third item calls for slight comment. Probably the constitution makers of the State of Illinois will not give serious attention to a proposal to fix in the basic laws the provision that there shall be no regulation of medical practice. The very idea is unthinkable in a matter of such vital concern as the health of the people. There should not be less but more stringent regulation to insure that those who safeguard our health and our lives should be of the highest competence.

These incidents serve to shake our optimism, but they should also serve as a counsel in the difficult task of bringing complete preventive medicine to the service of all men.

THE SERVICE OF THE DISPENSARY

MODERN MEDICINE begins in this issue the publication of a series of three articles from the survey of dispensaries made by the New York Academy of Medicine under the direction of Dr. E. H. Lewinski-Corwin, executive secretary of the Public Health Committee. These chapters are selected because of their particular interest to physicians. The titles are: "The Service of the Dispensary," "The Problem of Disease," and "Dispensary Patients."

A summary of the whole report was given in a recent issue by the *Journal of the American Medical Association*, sections on the organization, administration, and equipment are appearing in THE MODERN HOSPITAL, and still others will be published in the *Quarterly of the American Social Hygiene Association* and in the *Review of Tuberculosis*.

This study is one of the most important and far reaching ever made of dispensaries. The wide use of these institutions in New York City makes the findings of unusual value.

From the summary of the investigation it appears that there are in Greater New York 153 licensed dispensaries in which about 4,000,000 treatments are given annually. To encompass this amount of work, 3,680 sessions are held weekly, with about 8,000 hours of actual operation.

Eighty per cent of the patients came with complaints which required treatment in departments other than internal medicine. This means that a large part of the wage-earning class resorts to the dispensaries when in need of the services of specialists or special examinations and treatment for which they cannot afford to pay the private physician.

The study corroborates the findings of other investigations on the question of so-called "dispensary abuse." Two and two-tenths per cent of the patients were palpably taking undue advantage of the dispensaries; 79.4 per cent, because of their low economic status, were justified in seeking the dispensary for treatment; and the rest because they sought treatment which they could not get elsewhere at the prices they could afford to pay. This points to the need of pay clinics, and the committee suggests the adoption of a fee of fifty cents for such as are able to pay. This fee is within the reach of the majority of wage earners and would materially increase the present income of the dispensaries and enable them to provide necessary equipment, pay salaries to some or all of the physicians, and employ greatly needed clerical, nursing, and social service workers.

The committee found that in most of the institutions there was need of a clearly defined policy and of better executive direction. In the larger institutions it is felt that a full time executive should be employed.

No accurate figures were available as to the total amount of money invested in the dispensaries of New York City, nor were accurate figures to be had as to the cost of maintenance and administration. A conservative estimate, based on the reported expenditures for the year 1918 of thirty-four dispensaries in the United Hospital Fund, places the cost of maintenance and administration at $2,000,000 per year. Institutions representing such an investment and expenditure have a very definite responsibility to become institutions for efficient diagnosis and treatment, public health centers in their neighborhoods, and efficient training schools for doctors, nurses, and social workers, but thus far the New York dispensaries have failed to develop to the fullest extent their medical and educational opportunities.

In order to increase the efficiency of dispensaries, the committee cites some of the possibilities of efficient organization, and recommends reduction in the length of the period patients must wait prior to admission to the clinic. This can be

accomplished by a system of appointments, the feasibility of which has been demonstrated by the American Red Cross Clinic for Children at Le Havre, or by the principle of limitation of numbers. The application of either of these principles will not only reduce the waiting time of the patient but will prevent the swamping of clinic physicians with numbers of patients whom they cannot treat efficiently.

The committee deprecates the assignment of patients to different departments by lay registrars and, except where the diagnosis is obvious, recommends that a diagnostic division be organized to which patients may be referred for examination and assignment to the appropriate department.

To give patients the greatest benefit from medical skill, the equipment of dispensaries with all modern facilities for doing accurate diagnosis and efficient treatment is recommended. Reduction of the number of clinics and their re-grouping may sometimes help to improve the methods for assigning patients.

To retain the sustained interest of physicians, a medical organization correlating the dispensary service with that of the hospital in such a way as to give the younger physicians an opportunity for advancement is recommended. In detached dispensaries it is recommended that arrangements be made with medical schools for organizing post-graduate instruction in order that the whole field of clinical work of the city may be permeated with the spirit of research and teaching, and in order that all existing facilities may be put to the most useful purposes.

Adequate medical records are regarded as essential to good work and the scientific use of clinical material. The committee, however, found that adequate physical examinations were recorded in less than one-fifth of the cases treated in the dispensaries investigated. The more general use of the clinic secretary for the smooth and expeditious running of the clinic is recommended.

Investigations revealed an inadequate nursing personnel in the dispensaries, and to remedy this situation the committee recommends that more of the dispensaries connected with hospitals adopt the plan inaugurated in some institutions where a part of the course in the training schools for nurses is devoted to dispensary work, the course being so arranged that each of the pupil nurses has several months' experience in the dispensary under a head nurse.

The committee recommends that a Social Service Department be incorporated in the ad-

DR. ELMER E SOUTHARD OF HARVARD DIES OF PNEUMONIA

Dr. Elmer Ernest Southard of Cambridge, Mass., assistant professor of psychology at Harvard University and Bullard professor of neuropathology at the Harvard Medical School, and an eminent psychiatrist, died of pneumonia, February 8, at the Hotel Prince George, New York City.

Born in Boston, July 28, 1876, Dr. Southard attended Harvard University, receiving his A.B. degree in 1897; his M.D. degree in 1901; and an A.M. degree in 1902. He also attended Sneckberg Institute at Frankfort and the University of Heidelberg in 1902. He received the honorary degree of Doctor of Science from George Washington University in 1917. Just before his departure and also upon his return from abroad he was an intern and assistant in pathology in the Boston City Hospital, and was later visiting pathologist in the same institution. In 1904 he became instructor of neuropathology and was an assistant professor in the Harvard Medical School.

Dr. Southard was made Bullard professor in the Harvard Medical School in 1909. From 1903 to 1909 he had been assistant physician and pathologist in Danver's State Hospital for the Insane, and since 1909 was pathologist to the Massachusetts Commission on Mental Diseases. Since 1912 he had been director of the Boston Psychopathic Hospital, and at the time of his death was a director of the Massachusetts Psychiatric Institution at Boston.

Dr. Southard was assistant editor of the *Journal of Nervous and Mental Diseases*, *The Psychiatric Bulletin*, and *The Journal of Clinic and Laboratory Medicine*. Among his books were "Neurosyphilis," written in collaboration with Dr. H. V. Solomon; "Shell Shock and Neuropsychiatry," and the "Weekly Research Papers," which were written in collaboration with Dr. H. E. Fernold. He contributed to many periodicals and published an account of his researches at the Danvers State Hospital for the Insane. During the war he was a Major in the Chemical Warfare Service and also chairman of the Committee on Psychiatry and Neurology of the National Research Council.

In addition to being a director of the Bedford Hills Laboratory Bureau of Social Hygiene, Dr. Southard was a member of the American Academy of Arts and Sciences, the Association of American Physicians, the Massachusetts Medical Society, the American Neurology Association, the American Association of Pathologists, the Society of Experimental Biology, the American Psychopathol Association, the New England Psychiatric Society, the Boston Society of Psychiatry and Neurology, the National Epilepsy Association, and the American Genetic Association. He was formerly president of the American Medico-Psychological Association, and at the time of his death was president of the Boston Society of Psychiatry and Neurology.

He is survived by his widow, Dr. Mabel Austin Southard, a lecturer at Wellesley College, his mother, Mrs. Martin Southard of Boston, two sons, Austin and Ordway, and a daughter, Anne.

ministrative plan of the dispensaries and calls attention to the need for a concentration of effort on the part of all who are interested in social service work to secure a crystallization of function and procedure.

TWENTY-FIVE YEARS OF DIPHTHERIA SEROTHERAPY

A TIMELY review of the twenty-five years' use of diphtheria antitoxin in the reduction of diphtheria mortality appears in a recent *Bulletin of the Paris Academy of Medicine*.[1] The author reminds us it was on September 7, 1894, that Roux presented his famous *mémoire* on the value of serotherapy in the treatment of diphtheria before the International Congress on Hygiene and Demography at Budapest. Roux had reported on 300 patients with diphtheria who had received the antitoxin to the exclusion of all other forms of treatment and his results appeared so clear and so conclusive that he left a definite conviction of its efficacy among those who heard him.

The author recounts the successes of diphtheria antitoxin during the past twenty-five years and rapid spread of its use, and offers a word of hope for a further reduction in diphtheria mortality by an extension of the use of antitoxin.

Previous to the administration of antitoxin, the mortality from diphtheria was from 50 to 100 per 100,000, but these figures have been reduced to from 10 to 20 per 100,000 by the use of the anti-diphtheretic serum. The best results have been obtained in those countries and cities having the best developed health organizations where the antitoxin was distributed and administered most frequently.

Reference was made by Rous[2] to the cases of 3,971 children treated for diphtheria at the Children's Hospital in Paris between 1890 and 1893. Of this number, 2,029 died, making a case fatality of 51.75 per 100. Of those children receiving antitoxin treatment between February 1 and July 24, 1894, the case fatality was only 24.5 per 100. During the five years of war there were only 378 deaths among 15,271 cases of diphtheria treated in French army hospitals outside the war zone. This is equivalent to a fatality of 2.64 per 100. In the war zone there were 229 deaths among 11,433 cases representing a case fatality of only 2 per 100.

May we hope for even better results from the use of anti-diphtheretic serum? It is believed that by the prompt administration of antitoxin in the early hours of the disease, and by the use of this serum in suspicious cases even before confirmatory bacteriological evidence is available, that the mortality from diphtheria can be further reduced. In the past insufficient attention has been paid to the detection of carriers among convalescents. Patients should not be released from quarantine until nose and throat examinations no longer show the presence of the diphtheria bacillus.

A forward step in increasing the efficiency of antitoxin treatment has been the use of the intramuscular and intravenous methods of administration with the consequent saving of the most severe cases of the disease. Fear of acute anaphylactic reactions has been largely dispelled by the harmless use of repeated injections.

EMASCULATION OF OHIO HEALTH LAW

REFERENCE has been made in these columns on several occasions to the admirable Hughes act, passed last year in Ohio, which divided the state into 110 districts and provided for the appointment under the Civil Service of a full-time health officer and a public health nurse for each district. A technical legal decision brought the act once more before the Ohio Legislature for a necessary minor amendment; and the occasion was unfortunately utilized to substitute a wholly different bill, which permitted the health officers to serve on part time and removed them from the protection of the Civil Service law. The 276 applicants for the positions originally contemplated have been notified not to appear for oral examination and Ohio abandons her brief preëminence in the field of public health legislation. The principle remains, however, even though the experiment fails. The Hughes act will no doubt serve as an inspiration to other states which really desire to protect their citizens from preventable diseases.

INDUSTRIAL PHYSICIANS' MEETING

THE annual convention of the American Association of Industrial Physicians and Surgeons convenes at New Orleans on April 26 and 27 for a two-day session. A strong program is being arranged. The increased interest in the field of industrial medicine and surgery and the large growth in membership enlarges the importance of each successive convention. Industrial physicians will doubtless utilize the opportunity of attending the conventions on social work and tuberculosis and the medical association in New Orleans and St. Louis, held contemporaneously.

THE UNTILLED FIELDS OF PUBLIC HEALTH*

By C.-E. A. WINSLOW, Dr. P.H., Professor of Public Health, Yale School of Medicine, New Haven, Conn.

A SHORT time ago two Yale undergraduates came to my laboratory to consult me in regard to the choice of a career. One of them was the son of a public health administrator of the highest eminence; and they particularly wanted to know something about the field of public health, what it included, what was the nature of the work involved, what were the qualifications required, what the financial rewards, and the more intangible emoluments to be expected by those who might enter upon this career. I told them what I could of the current tendencies which to me seem to make public health one of the most stimulating and attractive openings lying before the college student of the present day; but I found that the answer to their question was by no means a simple one to formulate. The public health movement has been expanding so rapidly that what was "the new public health" fifteen years ago includes only the more conventional interests of the present day.

Public Health is the science and the art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will ensure to every individual a standard of living adequate for the maintenance of health; organizing these benefits in such fashion as to enable every citizen to realize his birthright of health and longevity.

It seemed to me as I talked with these young men that we need a formulation of current tendencies in the protean field of public health, and an outline of the lines of future development so far as they can safely be forecast. It is essential that the worker in this domain of applied science should see clearly the goal toward which he is aiming, however far ahead of the immediate possibilities of the moment it may appear to be. Above all, it is desirable that we should have a definite and inspiring program to lay before the young men and women of the country who hesitate in the choice of a career. On every hand we hear the question put by an eager young woman to the brilliant head of the Instructive District Nursing Association of Boston: "Miss Beard, I want to go into public health. What is it?" It behooves us to answer this question; for the greatest of all needs in this field is undoubtedly the need of a personnel, larger in quantity, and better in quality, than that which has been available in the past.

For these reasons I have determined to devote my address as retiring chairman of the Section on Physiology and Experimental Medicine to a tentative, if necessarily imperfect, formulation of the scope and tendencies of the modern public health campaign.

I spoke of the public health movement as protean, and it is indeed true that the emphasis in this field has shifted with a rapidity almost phantasmagoric.

To a large section of the public I fear that the health authorities are still best known as the people to whom one complains of unpleasant accumulations of rubbish in the back yard of a neighbor,—accumulations which possess those offensive characteristics which somehow can only originate in a neighbor's yard and never in one's own. Sanitation, the maintenance of cleanly and healthful environmental conditions, does indeed represent the first stage in public health. When Sir John Simon initiated the modern public health movement in London three-quarters of a century ago, his primary task was the elimination of the masses of accumulated filth which kept alive the pestilences of the Middle Ages. When General Gorgas undertook the task of making safe and feasible the building of the Panama Canal, he was in the same way confronted with problems that were primarily those of environmental sanitation. The removal of excretal wastes, the purification of sewage, the protection of water supplies, and the elimination of conditions which permit the breeding of insect carriers of disease, —these are always and everywhere the first tasks for the public health expert; and in the early phases of the public health movement in any country it is natural to visualize public health, primarily in terms of sanitation.

There is still much to do in this most fundamental branch of public health. That terrible

*Read before second annual meeting of the American Association for the Advancement of Science, St. Louis, Mo., January 2, 1920.

scourge of the Middle Ages, typhus fever, was only held in check during the war by a systematic and organized attempt to control the louse which carries the parasite of this disease; while the infection of bubonic plague, the black death of the Middle Ages, has spread broadcast throughout the world during the past twenty-five years, and has been conquered only by the vigorous eradication of the rats, ground squirrels, and other rodents which harbor the germ of this peculiar pestilence. The control of malaria, which takes a heavy toll of strength and vitality from the populations of our southern states and is estimated to cost the nation over $100,000,000 a year, is one of the mightiest tasks which confronts the sanitarian, but a task which, as the demonstrations conducted by the International Health Board have made clear, is easily within the range of practical accomplishment by means of systematic drainage and other measures taken against the mosquitoes which carry the germs of this disease. Malaria is with us always, but there are many maladies which, like yellow fever, arise from endemic foci in certain particular regions of the globe, and thence spread wherever the steamship and the railroad train can carry their inciting causes. Of recent years the bold idea has suggested itself of undertaking an offensive against these primary endemic foci of disease without waiting until the invaders cross our own national boundaries. In this way General Gorgas has carried the war against yellow fever into the enemy's own country at Guayaquil, and an organized campaign against such diseases on a basis of world cooperation, perhaps through the agency of the International Red Cross, is full of promise of achievement in the future.

There is much then to be done in the field of environmental sanitation; yet as the public health movement progresses the tasks of sanitation in the narrow sense are gradually accomplished and therefore become relatively less important. Constant attention is, of course, required to maintain the environment in a healthful condition; but in most civilized communities, in temperate climates, environmental sanitation has become a matter of routine, and the pestilences spread by polluted water and by insect carriers have ceased to figure as important factors in the death rate.

Control of Community Infections

As the aims of sanitation are approximately realized in a given community the attention of the health official turns from the water-borne and insect-borne diseases to the more subtle and more baffling maladies that are spread by direct contact from one individual to another. As typhoid, cholera, plague, and typhus fever approach the vanishing point, measles, pneumonia, and influenza became relatively more and more important. The control of community infections tends to replace the sanitation of the environment in the first rank of public health problems. The predominating tasks in this phase are tasks for the bacteriologist rather than for the engineer.

The leaders of the public health movement in the United States fifteen years ago were concerned primarily with problems of this sort. Their interest lay in the detection of incipient cases and of well carriers,—those individuals who while in normal health themselves, are cultivating and distributing from their bodies the germs of specific communicable diseases; in isolation, in bedside disinfection, in the breaking by any possible means of the vicious circle which transfers the discharges of the infected individual to the mouth or nose of the susceptible victim.

Artificial Immunity Effective

In the case of certain of the acute communicable infections we are fortunately able to invoke the use of another weapon against our microbic enemies by the prophylactic or therapeutic use of vaccines and immune sera and, so far, the production of artificial immunity against attacks of the microbes of disease has proved on the whole more effective than attempts at breaking the chain of contagion by isolation and disinfection. Smallpox, for example, has dwindled from the position of the chief pestilence menacing the human race to almost the condition of a medical curiosity, a result solely and directly of the use of vaccine. Typhoid fever has been eliminated from the army by an analogous procedure. Antitoxic serum has placed the control of diphtheria within our grasp, and diphtheria persists as a cause of death simply because of the failure to recognize the disease with sufficient promptness and to apply the protective measures at our disposal.

In general this second or bacteriological phase of the public health movement, while it can boast such remarkable achievements as those to which reference has just been made, is still far from the complete success which has attended the applications of environmental sanitation. It may be stated with some confidence that there is not one of the diseases originating in the non-living environment which we do not know how to control and which it is not entirely practical to control, given adequate funds and adequate personnel. Before some of the contact-borne diseases, on the other hand, we still stand almost helpless. We may be able to reduce the death rate from pneu-

monia by the use of protective vaccines, but there has been as yet no actual victory won sufficiently clear to admit of statistical demonstration. We can do much to mitigate the after effects of infant paralysis, but we have no effective method of controlling its spread. Before the ravages of a pandemic of influenza, such as swept the world in 1918, we are still practically without defense. Sanitarians have been accustomed to quote with horror the fact that bubonic plague killed 6,000,000 people in India during a period of ten years. Influenza carried off more than this number of persons in India in the four autumn months of 1918, and if it should recur again next year we should still be powerless to help.

Life Saving Health Officers' Task

There is much, then, to be done in the field of the community infections; many problems are yet to be solved by the bacteriologist and serologist before this group of diseases will pass under our control. Yet the suppression of community infections, like the sanitation of the environment, is but a part of the broad public health movement of the present day. The task of the health officer is to save lives, and to save as many lives as possible, by the intelligent application of the resources placed at his disposal. If he be wise he will direct his energies and his appropriations according to the indications derived from a study of vital statistics. He will apply his resources at a point where the greatest number of lives can be saved with the least expenditure of effort. From this standpoint there are two aspects of the public health program which tend, and rightly tend, to overshadow all the rest,—the campaigns against infant mortality and tuberculosis. These are the two lines of endeavor which promise the largest results in actual life saving; and in both these fields of effort the part played by sanitation and bacteriology in the narrow sense is a relatively small one. We can reduce infant mortality by the pasteurization of milk, by the elimination of flies, and by the protection of the baby from contact with infected persons; but these are, after all, incidents in a broad program which involves the education of the mother in the whole technic of infant care, feeding, clothing, airing, and bathing. What we are really aiming at is a reform in personal hygiene.

The campaign against tuberculosis offers another illustration of the same general principle. We can do something by providing a sanitary environment in which the worker is protected against vitiated air and harmful industrial dusts. We can do something by the control of the careless consumptive and the consequent reduction of the menace of specific infection. Our main weapon against tuberculosis is, however, again, the weapon of personal hygiene. The principal machinery upon which we rely is designed to detect the early case and to impose upon the individual in the home or in the sanatorium a regimen of daily living that will make it possible for his own tissues to wage a winning fight against the invading microörganisms. Once more, the problem is primarily a problem in the personal conduct of the individual life, and we see the teacher of personal hygiene emerging as a supremely important factor in the present day campaign for public health.

According to the Director of the Census the five principal causes of death in the Registration Area of the United States for 1916 with the number of deaths caused by each were as follows: Heart diseases, 114,000; tuberculosis, 101,000; pneumonia, 98,000; Bright's disease, 75,000; and cancer, 58,000. Of these five causes of death there are two, pneumonia and tuberculosis, in which the sanitation of living and work places, the isolation of the infected individual, and in the case of pneumonia, the use of sera and vaccines, do play an important part. Even with tuberculosis and pneumonia, however, education in personal hygiene fills a large place in the modern preventive campaign. Heart disease and nephritis may, of course, often be the end results of bacterial infection; but the immediate problem of their control is not to be sought along conventional sanitary and bacteriological lines. In the past they have indeed been considered as beyond the range of control measures of any kind. With these diseases, too, it seems clear, however, that education in personal hygiene offers large possibilities of effective results. If the weakness of the heart or arteries be known in time, the adoption of proper rules for daily living can at least postpone the fatal result, if it cannot successfully effect organic cure.

It is for these reasons that the public health campaign of the present day has become preeminently an educational campaign. There are those who maintain that because the public health authority alone possesses the power to enforce regulations with the strong arm of the law, such authorities should confine themselves to the exercise of police power, leaving educational activities to develop under the hands of private agencies. The actual amount of life saving that can be accomplished by purely restrictive methods is, however, small and such exercise of police power as may be necessary can only gain in effectiveness if it forms an integral part of a general campaign of leadership in hygienic living.

We have now added to the function of the sanitarian and the bacteriologist that of a new figure in the public health campaign, the teacher of personal hygiene; but we cannot stop here if we are prepared to follow the courageous public health official in his determination to adopt whatever machinery may prove necessary for the saving of a maximum number of lives at a minimum cost.

Education in personal hygiene is in part a general propaganda applicable to all alike. There are certain fundamental principles as to food, fresh air, exercise, and rest, which every one should know in order to manage wisely the delicate physical machine entrusted to his charge. Unfortunately, however, each living machine is in some respects different from every other living machine, and in many cases deviations from the normal are so marked that they demand fundamental modifications in the regimen of daily life. The man with the weak heart needs less exercise, the man with weak lungs more air and more rest, the man with diabetes a special kind of food. In addition to the hygiene for the normal, which we may teach to all, there is a hygiene for the abnormal which requires an adaptation to each specific case. But it is obvious that the teaching of this kind of hygiene demands first of all an individual diagnosis. We are here face to face with the problem of the relation of the physician to the modern public health campaign.

Arbitrary Lines Being Obliterated

In the past a sharp line was drawn between the measures taken by public health authorities to check the spread of epidemic disease and the daily routine of the practitioner in the treatment of the individual case. The first was public health, the second private medicine. With the passing of every year it becomes harder to draw such a sharp line, more difficult to say where public health should end and private medicine begin. The history of medical school inspection offers an excellent example of the tendency to obliterate such arbitrary lines. The physician was first sent into the schools in Boston in 1894 to perform a definite police function,—to detect cases of communicable disease and by so doing to protect one child against the danger from another. If it had been proposed at that time to organize clinics for free treatment of disease among school children, the proposal would probably have been denounced as socialism of the most dangerous kind. Just so soon, however, as the physicians began actual work in the class room they found that acute infections, passing from one individual to another, played but a small part in the total burden of preventable disease borne by the children in the schools. They found defects of teeth, defects of vision, defects of hearing, enlarged glands. Nine-tenths of the time of the school inspector of today is devoted to defects of this kind. He is no longer protecting one child against another. He is helping each child to attain its maximum possibilities of health and efficiency.

School Nurses as Health Agents

The discovery of non-contagious physical defects was the first step in bringing the public health movement into intimate contact with the individual child. Very soon, however, it became evident that the detection of remediable defects was of little value unless something was done to remedy them, and the school nurse was drafted into service to follow the child into the home and to persuade the parents to take the measures indicated by the medical examiner's report. The development of a school nursing service as an educational agency of this sort resulted in New York City in increasing the proportion of defects actually treated from 6 to 80 per cent. In a certain number of cases, however, a new difficulty arose. Remediable defects were present and the parents were willing and anxious to have them treated, but they were without funds to pay for the special medical care that was needed. The next step was as logical as the preceding ones. It involved the establishment of school clinics for the treatment of children unable to obtain the necessary care in any other way. So, with the establishment of nose and throat clinics, eye and ear clinics, and dental clinics for the school child, the obliteration of the line between public health and private medicine was well-nigh complete.

If it is good public policy to provide for the school child whatever machinery is necessary to make possible the attainment of a reasonable standard of physical health, it is difficult to see why the same arguments do not apply to the adult as well. As a matter of fact, exactly the same tendencies to provide (1) diagnosis, (2) hygienic advice, (3) treatment when necessary, are already manifest in our tuberculosis clinics and our venereal disease clinics, and are beginning to develop in connection even with diseases of the heart and arteries and cancer. If it is sound economy to provide for the early diagnosis and sanatorium treatment of tuberculosis, it is just as sound to provide for the early diagnosis and surgical treatment of cancer. The two diseases are equally dangerous and equally burdensome to the community; they are equally preventable if the right educational and clinical procedures are organized for their control.

From both sides of the artificial boundary line

between public health and private medicine comes the appeal for a closer correlation. The public health worker needs the physician because in so many diseases education depends on diagnosis and demands the application of medical skill. The farsighted physician is equally eager to link up his science with the public health program, because on his side he realizes that medicine can never attain its full potentialities of service unless it is made really preventive, through some type of effective professional and social coordination. It is a striking fact that in spite of the great advances in medical science, diseases like heart disease and nephritis and cancer, which have been handled in the past along strictly medical lines, have shown no decrease comparable to that which has been manifest in the group of maladies with which the sanitarian has dealt. This is not because medical science is helpless, but it is because medical knowledge has generally been applied only when disease has gone so far that the damage is irremediable. Medical knowledge will be highly effective only when applied in the incipient stages of disease. When this comes to pass, "preventive medicine" will become a reality and not merely a catch word.

How to Obtain Expert Service

It is not for us to say today in just what fashion the reorganization of medical service which will make it effective for prevention can best be brought about. In the working out of such a scheme there must be, first of all, within the profession itself, effective coordination of specialties in clinical and laboratory lines to provide the type of expert service which is furnished by our best hospitals and which no individual private practitioner can possibly supply. In the second place, such organized medical care must be made available not merely for the very poor and very rich, but for the entire community, for those who can afford to pay the whole or a part of the cost of the service they require, and for those who cannot pay at all. Finally, if medical care is to be made really preventive in its application, its cost must be so distributed as to encourage systematic recourse to the physician as an agent for the detection and control of incipient disease, rather than as a last resort when illness has become too grievous to be borne.

There are those who believe that these ends may be attained through group medicine, and it is interesting to notice that very similar ends have actually been reached in the nursing field through private initiative as manifested in our best visiting nurse organizations. There are others who claim that medical and nursing service can best be provided in connection with a plan for sickness insurance; and there are still others who urge that the insurance problem should be handled as a distinct and separate one, and that the early diagnosis and preventive care of incipient disease should be attained through a definite system of state medicine.

The working out of the best plan for securing such ends as these is a fascinating task for the publicist of the future, and it is quite possible that the problem may be solved in true Anglo-Saxon fashion by no single logical procedure but by diverse methods, suited to local ends and local circumstances. The remarkable developments during the past ten years in the field of industrial medicine may have a wide bearing on the general solution of our problem as a whole. Some 900 different industrial establishments employ at this time 1,500 industrial physicians; and the plant hospitals under their charge, from first aid dressing stations, are developing into educational centers, diagnostic clinics, and laboratories for the study of industrial physiology and vocational guidance and rehabilitation.

Health Related to Economic Level

We have seen the emphasis of the public health campaign move steadily inward from the environment to the individual. The primary interest of the health officer has been transferred from the swamp and the dung heap to the control of community infections and thence to the detection of non-contagious physical defects and the hygienic guidance of the individual living machine.

In the development of the public health campaign to the realization of its fullest opportunities there is taking place today a swing of the pendulum backward to a new interest in the environment, but an environment of a nature very different from the simple environment with which Simon dealt. General Gorgas, at Panama, fully grasped the significance of the wider and more subtle environment which most of us are just beginning to glimpse as an essential problem in the public health campaign. He eliminated yellow fever and malaria by the drainage of marsh lands, but he attempted to deal with pneumonia by raising the wages of the employees upon the Isthmus; for he realized that in the case of this and many other diseases the most effective weapon at our disposal is the building up of general vital resistance, which depends upon the maintenance of a satisfactory social and economic level.

Dr. Emmett Holt has said that there are two causes of infant mortality,—poverty and ignorance. In the infant welfare movement, the anti-tuberculosis campaign and every other field of

public health, we come sooner or later to a realization of the fact that education and medical and nursing service, while they can accomplish much, cannot cope successfully with the evil effects of standards of living too low to permit the maintenance of normal physical health.

As I have elsewhere pointed out, in the Johnstown survey Miss Duke tells us that the infant mortality in one ward was 271 deaths per 1,000 births, against 134 for the city as a whole, and 50 for the ward which showed the lowest rate, and the explanation is that "This is where the poorest, most lowly persons of the community live—families of men employed to do the unskilled work in the steel mills and the mines." Dr. Sydenstricker and his associates in the United States Public Health Service, in a report on the relation between disabling sickness and family income among cotton mill operatives in South Carolina, find that a monthly income equivalent to less than $12 per person, on an adult male unit basis, the sick rate was 70.1 per 1,000; with an income between $12 and $14 it was 48.2 per 1,000; with an income between $16 and $20 it was 34.4; and with an income of $20 and over it was 18.5.

We can conclude from these figures and from many similar investigations that poverty and sickness are closely correlated. We cannot conclude that the poverty is responsible for the excess of sickness. In some instances the relation of cause and effect may be reversed. In other cases both poverty and disease may be due to underlying inheritance. People do not usually live in the poorest quarters of a city or work at is underpaid employments by choice or by accident. In general, and on the average, we shall find in such districts and such employments a concentration of tuberculous stock, of alcoholic stock, of feeble-minded stock,—poor protoplasm and a bad environment supplementing each other in a vicious circle.

No one can perhaps tell just how far poverty in such cases is the real and effective cause of the failure to achieve and maintain a normal standard of physical health. It is clear, however, that there is a certain standard of income below which the maintenance of health is impossible; and it seems reasonably sure from the studies of Royal Meeker of the United States Bureau of Labor Statistics that a certain not inconsiderable proportion of the population of the United States has today a family income below that figure.

If an initially normal family cannot gain a livelihood adequate for its minimum physical needs, there is evidently a problem of social readjustment which our nation must face as a fundamental of post-war reconstruction; but what shall we say of the family which on account of inherent physical or mental defects is unable to reach a minimum level under a wholly fair and equable basis of compensation? There are but two alternatives as I can see it, since the moral sense of mankind repudiates the rigorous application of the principle of unhindered natural selection. We can let the combination of defective protoplasm and crippling environment accomplish the major portion of its work and then salvage what we can from the wreck by some form of institutional relief; or we can apply our social energy and our community funds to make good the deficiencies in the beginning. I have little doubt as to which will be found in the long run the cheaper way, and I am quite certain that the preventive method will prove more conducive to a high national morale.

The canker of disease gnaws at the very root of our national strength. The sufferers are not few or insignificant. They are the bread winners for at least a third part of our population. That they have causes of disease indolently left to blight them amid their toil. . . . is surely an intolerable wrong. And to be able to redress that wrong is perhaps among the greatest opportunities for good which human institutions can afford.—Sir John Simon.

If the foregoing outline of the problems of public health be accepted as correct, it will be obvious that the field as thus visualized is no small and restricted one. The claim to so large a province will be denied by many, within as well as without, the public health profession. The logic of the situation and the tendencies of social development are, however, sweeping the public health movement forward to a future of wider possibilities than those dreamed of by its own protagonists. If we are looking to the future, we must conceive our subject in terms no smaller than those of the following definition.

Definition of Public Health

Public health is the science and the art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and

nursing service for the early diagnosis and preventive treatment of disease, and the development of the social machinery which will ensure to every individual in the community a standard of living adequate for the maintenance of health.

Public health conceived in these terms will be something vastly different from the exercise of the purely police power which has been its principal manifestation in the past.

Even today it is still possible to make an effective argument for increasing health department budgets by showing that appropriations for the protection of health are in most cities far less than those which are made for police and fire protection,—matters of far less moment in actual possibilities of community service. As a matter of fact, the police department and the fire department furnish criteria much too modest for the public health department of the future. It is rather to education that the possibilities of public health should be compared. I look to see our health departments in the coming years organizing diverse forms of sanitary and medical and nursing and social service in such fashion as to enable every citizen to realize his birthright of health and longevity. I look to see health centers, local district foci for the coordination of every form of health activity, scattered through our cities, as numerous as the school houses of today and as lavishly equipped; while the public health services of the city and state will constitute a corps of experts comparable in size and influence to the great educational organizations of the present day.

Specialties Which Contribute

In the development of the public health campaign of the future along such lines as these it is obvious that many different experts, of fundamentally distinct training, must contribute their special resources to the common task. Ignoring all minor specialties, there must be at least the following seven types of highly qualified persons in this field: the physician, the nurse, the bacteriologist, the epidemiologist, the engineer, the statistician, and the social worker.

In addition there must be inspectors to supervise sanitary conditions, housing conditions, food stores, and the like, for whom no special training is provided anywhere in this country, but who should be offered brief practical courses to fit them for the relatively modest duties which their task entails. Finally, there is the administrator who organizes and develops the work of all the rest.

The physician in the public health field practises medicine, but with a difference, in that the goal before his eyes is prevention as well as cure, and that he has always in view not merely the individual but the community as well. In the infant welfare station and the school clinic and the tuberculosis dispensary he visualizes not merely the individual case, but its family environment and its physical background. He is constantly striving to find the incipient causes of disease and to deal with those causes before they reach their deadly fruition. He must be much more than a physician in order to fulfill this task; for he must have a knowledge of bacteriology and sanitation, of health administration and statistics; above all, of social relationships and social machinery which the curriculum of even the best medical schools cannot attempt to supply.

Health Nurse Must Be Health Teacher

So the public health nurse must be a trained nurse skilled in the relief of suffering and the bedside care of the sick, but she must be much more. Her work is primarily that of the health teacher, the messenger who carries into the home and interprets to the individual mother the gospel of good health. She must work largely alone, not under the immediate direction of a physician. She must know her bacteriology and her physiology, her sanitation and hygiene, well enough to teach their principles to others; and she, too, must deal with the individual, not merely as an individual, but as an element in a complex social group.

The bacteriologist in the laboratory and the epidemiologist in the field are two more of the specialists needed, whose work is concerned primarily with the war against the community infections. The former offers aids in early diagnosis and prepares sera and vaccines for the prophylactic and therapeutic treatment of these diseases; the latter, by his detective work, makes it possible to trace out the subtle pathways of infection by which they spread from one person to another through the complex web of community life.

The public health or sanitary engineer is again an engineer *plus*. He must have mastered the underlying sciences of physics and chemistry, of structures and hydraulics; and he must also be familiar with the technical applications of his art to the particular problems of sewage disposal and water supply, ventilation, illumination, and the like.

The statistician correlates and analyzes the records of births, deaths, and illnesses, keeping an expert finger, as it were, on the pulse of the nation's health. His work is the bookkeeping of public health, indicating the lines of profitable

expansion and furnishing us with the credit balance of lives saved to the community as a result of various public health endeavors.

In the case of each of these experts, and in the case of the social worker who is operating in the field of public health, there is required sound elementary education in some fundamental branch of science, with the addition of specific training in its applications to the field of public health. For the nurse who desires to become a public health nurse there are offered four-month and eight-month courses of special training in public health nursing. The physician who desires to become a public health physician, the engineer who desires to become a sanitarian, the bacteriologist who desires to become a public health bacteriologist, the social worker who desires to apply a fundamental knowledge of the principles of social readjustment within the field of public health, must similarly undergo a special training if their services are to be made promptly and fully available. It is for this purpose that our leading universities and technical schools offer the Certificate in Public Health, which, like the Master's degree, is the equivalent of a year's graduate study. The Certificate in Public Health course gives to the medical graduate the special training needed to equip him for the application of medicine in the field of public health, and in the same way enables men and women who have had college training in the fundamentals of bacteriology, engineering, sociology, or statistics to fit into their special places in the general scheme of health protection.

Medical and Public Health Training Advantageous

To turn from these special phases of the public health campaign to the organization of the movement as a whole, it seems probable that the ideal public health administrator of the future will be the man or woman who has been first medically trained and has then specialized in a school of public health. If I am right in my belief that the public health movement of the future will go far in the direction of including medical and nursing service within its ample bounds, it is clear that a man who has both a medical and a public health training will possess peculiar advantages as an administrator. It is for this reason that the principal eastern universities offer the highest degree in this field, the Doctor of Public Health, only to medical graduates, and require that it be earned by a rigorous course of two years of academic study.

It will be long, however, before the supply of doctors of public health is nearly adequate to the demand, and for some time to come administrative positions, as well as laboratory and statistical positions and those concerned with social reorganization, will be open to the college man or woman who devotes a single graduate year to study for the Certificate in Public Health.

It can be said with very literal truth of the field of public health today that the harvest is ready and that the laborers are few. On all hands there comes to us the call for bacteriologists and statisticians, for industrial physicians, and school physicians, for public health nurses, and for health officers. The American Red Cross is inaugurating a nation-wide campaign for the development of health centers throughout the country. Each one of the thousands of health centers to be started under this plan will call for an expert personnel, which does not exist at present.

Health Work Offers Career

The science and the art of public health have progressed to a point where they can render to the public a service to be measured in the saving of hundreds of thousands of lives in this country every year. Public authorities and private agencies from one end of the land to another are realizing these possibilities of service and are ready to provide the necessary funds and to give the necessary powers to properly qualified experts. The lack in the whole scheme of things at the present moment is the lack of personnel. As a prominent official of the Rockefeller Foundation said to me the other night, "The way they are appropriating money for public health in the southern states frightens me, because we haven't the men to send to them to help them spend it wisely." We stand, I believe, at the beginning of a new phase of human history, a phase in which the physical and mental health and efficiency of the human being will be transformed by science as the physical background of civilization has been transformed in the past half century. In the name of the need that confronts us for the personnel to carry on this work, I believe we have the right to say boldly to the college men and women of America that we need them in this great business. We can promise to the college graduate, whether his leanings be toward work in the laboratory, toward sanitation in the field, toward the tasks of social propaganda and social reconstruction,—we can promise to the medical student,—and we can promise to the graduate nurse,—that each and all of them will find in the public health movement of the future careers which will compare favorably in security and in material rewards with the average return which is won by the college and medical graduate in

other fields. Above all, we can promise the opportunity of a kind of service which brings a satisfaction deeper than any material reward.

There are great unsolved problems waiting for the Pasteurs of the future. Influenza, pneumonia, cancer, and the rest of the unconquered plagues will some day yield to the patient assault of science, and it may well fall to the lot of young men who are entering our laboratories today to write the obituary of these diseases as Walter Reed did that of yellow fever in 1900. Two of Reed's letters to his wife after he and his associates had made the great discovery that insured the conquest of yellow fever in the ensuing year are so full of the solemn dignity of such a victory that I will quote them.

Six months ago, when we landed on this island, absolutely nothing was known concerning the propagation and spread of yellow fever—it was all an unfathomable mystery—but today the curtain has been drawn.

And later, on New Year's Eve, he wrote:

Only ten minutes of the old century remain. Here have I been sitting, reading that most wonderful book, "La Roche on Yellow Fever," written in 1853. Forty-seven years later it has been permitted to me and my assistants to lift the impenetrable veil that has surrounded the causation of this most wonderful, dreadful pest of humanity and to put it on a rational, and scientific basis. I thank God that this has been accomplished during the latter days of the old century. May its cure be brought out in the early days of the new!

Need for Sanitary Statesmen

Yet we need not wait for the great discoveries of the future to make the public health campaign of the present day bear fruit. We want sanitary statesmen as much as investigators. We need organizers and propagandists for the cause of health, capable of building wisely the great scheme of health protection of the future and of enlisting in its support the enthusiastic cooperation of the peoples of the earth. To the administrator, as much as to the investigator, comes the consciousness of a reward for his labors, fuller and more immediate than that which can be earned in many walks of life; for he can know that in a given city in a given year so many hundreds or thousands of men and women and children are alive and well who would have been in their graves except for him. What old Sir John Simon said of industrial diseases is true of every kind of preventable malady which afflicts mankind.

The canker of disease gnaws at the very root of our national strength. The sufferers are not few or insignificant. They are the bread winners for at least a third part of our population. . . . That they have causes of disease indolently left to blight them amid their toil . . . is surely an intolerable wrong. And to be able to redress that wrong is perhaps among the greatest opportunities for good which human institutions can afford.

SURGEON GENERAL CUMMING, NEW CHIEF OF PUBLIC HEALTH SERVICE

DR. HUGH S. CUMMING has received the appointment as Surgeon General of the United States Public Health Service, to succeed Dr. Rupert Blue.

Dr. Cumming was born at Hampton, Va., August 17, 1869. He was graduated in medicine from the University of Virginia in 1894. On May 25 of the same year he was commissioned as assistant surgeon, passed assistant surgeon five years later, attained promotion to surgeon March 15, 1911, of senior surgeon November 8, 1918, and was appointed Assistant Surgeon General March 6, 1919.

For a number of years Dr. Cumming was quarantine officer at Hampton Roads. Most of his work during his quarter of a century of service has been spent in quarantine work. At the time of his appointment he was in Naples, fighting typhus, and it will be some weeks before his work in that city, Constantinople, and Paris can be completed.

Dr. Cumming takes the position as chief executive of the United States Public Health Service at a time when the issues are more pressing and the work more exacting than ever before. The difficult tasks which the Department faces at this time include the rehabilitation of the thousands of soldiers who contracted tuberculosis during the Great War, and of the soldiers incapacitated mentally or suffering from nervous disorders as a result of their overseas experience. The ravages of the two successive influenza epidemics are to be combatted, and means evolved through research for the control of succeeding waves of this disease.

Preventive medicine is to be brought to the fore and the increasing demand of medical agencies for Federal leadership call for reorganization of the service to meet the standard of a new era in public health.

REVISED CASUALTY LIST

Final revised figures of American Army casualties in the war have been announced by the Adjutant General. They show that the total casualties were 302,612, with deaths numbering 77,118. Prior figures, based on weekly casualty summaries issued by the War Department, gave the total as 293,061, with 77,635 deaths.

The revised figures are as follows:

Killed in action	34,248
Died of wounds	13,700
Died of disease	23,430
Died of accident	2,019
Drowned	300
Suicide	272
Murder or homicide	154
Executed by sentence of General Court Martial	10
Other known causes	489
Causes undetermined	1,839
Presumed dead	650
Total dead	77,118
Prisoners unaccounted for	15
Prisoners died	147
Prisoners repatriated	4,270
Total prisoners	3,432
Wounded slightly	91,189
Wounded severely	83,390
Wounded, degree undetermined	46,480
Total wounded	221,050
Missing in action	3
Grand total	302,012

INFLUENCE OF WAR CONCEPTS OF MENTAL DISEASES AND NEUROSES*

By SIDNEY I. SCHWAB, M.D., Professor of Clinical Neurology, Washington University, St. Louis, Mo.

A SCIENTIFIC friend of mine has suggested that in the next war, and he seems to be convinced that there will be a next war, an army of scientists will be mobilized at the first indication of hostilities. He foresees that such a scientific army will accompany the fighting contingents wherever they go, in order to take immediate advantage of the extraordinary opportunities for scientific exploration that a war in the modern sense of the word affords. His point, and therein is its novelty, lies in the fact that such a scientific army will have no direct military object, but will be organized to take advantage of the free exploitation of the treasures of civilization which a state of war spreads over the face of the earth. War in this sense becomes a kind of scientific emergency, and the free play of scientific minds across the field of this emergency should yield a rich harvest.

WAR GAINS IN NEUROPSYCHIATRY

The chief gain to psychiatry as a result of war experience lies not so much in new discovery as in a new basis of interpretation.

Contributions to the literature are more and more on the basis of conduct interpretation, seeking an understanding of the war psychoses as instinctive protective reactions of the nervous system.

The difference between war psychoses and the defensive reactions of the maladjusted individual in civil life is one only of degree. The remedy for both lies in a mental hygiene, which induces the patient to face his problem frankly and see it through.

War Contributes to Science

That wars hitherto have not been rich in scientific conquests is explained by the fact that in no war has there been an organization planned to add to the sum of knowledge by utilizing the research opportunities unloosed by nations fighting for their existence. However fanciful this notion may be, it holds an element of truth and this truth is the propelling motive behind this meeting of the American Association for the Advancement of Science. In the war an initial organization of this kind was attempted, chiefly in those branches of science the application of which had a distinct military or combative purpose. Physics, chemistry, geology, metereology, and medicine all have a military significance. In the final period and up to the armistice the organization of such departments had reached a definite degree of excellence.

In war there is a curious change in the habits and thought of a people, chiefly due to the fact that there is a state of emergency, upon the proper solution of which the safety and existence of that people may well depend. It is here that the trained mind of the scientist comes face to face with his opportunity, and it is to his everlasting credit that in this crisis he has not been found wanting. The war against ignorance is transferred from the laboratory and the classroom into the actual area of conflict and the same method which is effectual in the one place is effectual in the other. Search for truth is concerned but little with motives except those inherent in truth itself; and response of scientific spirit, activated by the call of dire necessity, is as true to the underlying laws of scientific reasoning in a hut near the front lines as in a well lighted and warmed laboratory on the picturesque campus of a university.

You can visualize, then, a body of scientists as an integral part of the armed forces in the next war, prepared to gather from the destructive agencies that will then be let loose such data of new knowledge as may add to the hard won assets of man's urge towards a completer understanding of the universe. The tendency to see in destructive happenings elements of gain is but a reflection of the spirit of rationalization. It is man's excuse for his intemperate and illogical ways of doing things. It lies behind the question so often asked of those returning from overseas: "What has been the gain to you or to your branch of knowledge out of the more than four years fighting?" The purpose of this paper is to put that rationalization in concrete form by telling in a brief way what one department of medicine has gained and to point out how that gain, or illumination as I choose to call it, has resulted from the application of pre-war experiences often of highly theoretical nature, developed in many

*Read before the American Association for the Advancement of Science, Section on Physiology and Experimental Medicine, St. Louis, Mo., January 2, 1920.

laboratories and from the accumulated experiences of many clinical students.

The problem concerns itself with the nervous system of a soldier in the face of the destructive agencies of modern warfare. This nervous system had to face the shattering force of high explosives, machine gunning, unutterable weariness, and all the other agencies of destruction that the scientific energies of the human mind bent on extermination could devise. Let us assume for a minute that the nervous system of the soldier was made the object of a series of laboratory experiments in which every sort of disintegrating force was applied to it in order to see, observe, and measure the resulting phenomena. A wealth of information of the greatest value would assuredly come out of controlled and carefully planned tests of this kind. The war was such a laboratory on a colossal scale and with an enormous number of experiments, with the difference, however, that in the war the experiments were neither planned nor controlled; there were little laboratory equipment and no important body of trained observers or assistants. Such as they were, they had mostly other things to do, chiefly the task of getting the same laboratory subjects back to the fighting lines as quickly as possible so that they could be experimented on again.

Value of Uncontrolled Experiments

As a result of these uncontrolled experiments what new thing came out and how much was added to the total of our knowledge of the nervous system as a whole? In other words, because of the war experience do we know more about the nervous system? If we do, how is it possible to make use of this gain towards solving the problems of the civilian conflicts which this same nervous system must meet? It can be conservatively stated that at least 20 per cent of the total casualties, exclusive of disease and infections, was concerned either directly or indirectly with the nervous system, that is, wounds of the peripheral nerves, spinal cord, brain; and that shock to the nervous system unaccompanied by demonstrable changes in the anatomical integrity of the nervous system called shell shock or war neurosis. In the American army alone at least 20,000 individuals would fall in these categories. This then, constitutes the material for investigation, if a body of neurologists had been sent over for that purpose. Is it any wonder that this friend of mine should have been impressed by the scientific opportunity offered by a great war? Is it not a matter of importance that the next war should find scientific preparedness a little more forehanded?

The material for study was much more extensive than this, for it is to be remembered that the medical examination of hundreds of thousands of recruits in the United States has brought out facts of the greatest importance. There was given an opportunity to study the nervous system of four or five million of easily controlled youthful male citizens,—prospective soldiers. After the obviously unfit were excluded the normal residue was transferred to training camps where it became, or might have become, an object of neurological study from the point of view of the reaction to military training and military life. Then, sifted again, with the rejection of the unfit, these soldiers were sent overseas, further trained on foreign soil, and directly prepared for active participation in the combat. Here again the unfit were rejected and those remaining, wholly sound and fit to be combatants, were sent to the forward areas and lived thereafter under conditions of actual fighting. The nervous system of that army was then subjected to the physiological test of meeting series of destructive influences, and the results as wounded or sick soldiers gathered together in special or base hospitals for treatment and such study as the exigencies of the situation afforded. After the armistice the uncured residue were sent home as charges upon the public health service where further study can be carried out.

This merely sketches out the material that a war furnishes for study, a war which engages the whole man power of a nation and where the total physical strength of a people is called into activity. In spite of the fact that this war could not altogether be looked at as a series of countless physiological experiments, there came out of it much to stir the imagination and awaken the enthusiasm of the neuropsychiatrist. It may be regarded chiefly as a kind of illumination, a sort of light thrown unexpectedly into dark places, giving often enough merely a fleeting glimpse of what the problem really is and how a solution may come about. A glimpse around the corner may express this more fully. A science is enriched not by facts alone. Very often a shifting point of view, a new insight, a novel background, are the permanent gains and lead the way to more constructive thought and experimentation.

The war has enriched neurology by the stimulus it has given to numerous workers in this field, by the opening up of new pathways, and in encouraging students in its ultimate possibilities.

The nervous system is a very complicated structure out of which develop and upon which are based groups of complex mechanisms. These have to do with the physiology of the nervous system,—chiefly with the problems of the integration of

nervous impulses to and from the various centers of coordination; also, with the development of functions of consciousness and personality. Each and all of these may show reactions of an abnormal kind as a result of the material and emotional shocks of warfare.

If, for example, a machine gun bullet severs completely the ulnar nerve, the resulting paralysis of the muscles supplied by that nerve and the accompanying sensory disturbance, from the point of view of a laboratory experiment, present a complete conduction break in that nerve. The phenomena that follow are of two kinds: one groups itself about the anatomical changes produced in the distal and proximal part of the nerve deprived of its nutritional cells in the spinal cord, the degenerative action at the point of severance, and the tissue changes resulting in the section of normal nerve fibers and its replacement by fat and other abnormal tissues. If the severed nerve is re-united by suture or if there is a bridging of the space of separation, there develops a reaction of functional readjustment, an effort at regeneration which sets forth the physiological problem and frames the anatomical picture. The other group concerns the individual deprived of the use of his ulnar nerve by the failure to unite. If the period of regeneration is unduly prolonged, he takes note of the experiences which accompanied that injury and gives way to the depression and discouragement, and, falling a victim to the organization of such a state, there develops a change in his personality which may finally completely overshadow the ulnar injury. Follow that soldier to his home after discharge from the army and observe that he comes back as a handicapped man to whom the necessary adjustment to a different kind of employment comes hard or impossible. Think, then, of the long contemplation of his injury, the notion that the government should be at least materially concerned with his plight, his disappointment at the reception which a wounded defender of his country obtains, the economic and social responsibility piling up on him, and other things of a like nature, and you can sense something of the consequences of that simple military experiment performed in the laboratory of the Argonne Forest. This sketches in a crude fashion a phase of the problem which neurology has had to face in this war, and this is a simple example.

Here is another: A soldier receives a fragment of a high explosive shell in his cortex after it had fractured a part of his skull. With return of consciousness and after his wound has been healed, with the fragment removed, he finds that he can move his right side only with great difficulty and that he is unable to pronounce the word which is in his mind, nor can he express an idea clothed in the words which seem to him present in his consciousness. He is paralyzed and aphasic. His recovery is slow. He returns home able to walk with a limp, but unable to speak or write with his former facility. Some time later he becomes the subject of a convulsion and there develops slowly but progressively a condition of dementia, with such a change in his personal make-up that he must be removed from the social niche which he formerly occupied, and from his normal social environment.

Development of Defense Amnesia

The third example is of a different kind, and this experiment was performed some fifteen thousands times, at least, in the American Expeditionary Forces, some eight hundred thousand times in the French army, and more than that in the English divisions. A soldier, after some fatiguing experience and possibly a period of sleeplessness, is subjected to concussion by the explosion of a shell which, falling in his neighborhood, renders him unconscious. He is tossed in the air, and his last remaining gesture after he completely passes out is a gesture of defense against the onward rush of the air compressed about him. He partially regains consciousness in some hospital far removed from the scene of this experience, and finds, much to his astonishment, that his arms are in a state of constant movement, carrying out the defensive gestures with which he ended his last conscious moment. On examination by his medical officer it is found that he cannot feel the prick of a pin on one side of his body and that he is unaware of the position on one side of the smaller joints as they are moved in testing for his sense of position. He has at first only a vague idea of what has happened to him, but with returning consciousness, more of the picture and its attending horrors rise up in his mind. He recalls with a remarkable degree of vividness that his chum who was next to him had disappeared in a blinding flash of some explosion and that portions of the disintegrating body had spattered over him. This memory and the attendant circumstances fill him with such intense horror and arouse in him such a degree of intense emotional reaction that suddenly the whole incident, together with many that preceded and followed it, are blotted out of his mind. He develops a defense amnesia, and a break in the continuity of his memory stream results. This defect in consciousness acts like a foreign body, giving to him the sensation of something strange and queer, something that dissociates his personality in that

particular segment from reality. In this state he lies in his hospital bed, the prey to all the agonizing emotions resulting not only from a serious shock to the nervous system as such, but those due to a sense of mystery and misunderstanding.

This exemplifies a picture of shell shock or war neurosis, and not a very serious case as it happens to be,—such a one as has been cured by the hundreds in all the armies. It is necessary to note that in the last example of injury to the nervous system nothing tangible has been produced in the way of a destructive process in the tissues of the brain, but there has been brought into action a curious and interesting reaction of the nervous system,—the primitive reaction of defense, resting upon the instinct of self-preservation and activated by the protective emotion of fear. For the time being, at any rate, the individual so shocked is in no condition to repeat the experience that has brought him to this condition, and this protective neurosis will exist until his organism is again fit to take up military activities. The fixation of these symptoms and their elaboration into a more permanent system of defense can be prevented by skillful treatment.

The Role of Neurology in Medicine

It is something of a task to put down in a definite way just what the war has given to neurology and to point out in a positive fashion just what and where the gain has been. Even a record of new facts or new ideas will not convey the essential thought that through the exigencies of war neurology has come to something of its proper place in the domain of medicine. There has arisen the idea that in civil life, as well, there occur conflicts from which the nervous system comes out shocked and traumatized in the same essential manner that the nervous system of the soldier suffered in the more incisive and immensely more shattering conflicts over there. The social and economic stresses with which our world is filled, plus the incidence of various diseases that seem to be the necessary accompaniment of our civilization, produce a similar degree of receptivity to shocks of all kinds that the more resistant nervous system of the soldier, in the face of the more acute and more generally physical shocks of the battle area, had to endure.

The current of thought that runs in the usual post-war discussion of the profit and loss that has arisen out of the war centers about the question as to methods by which the benefit of this experience may be translated into civilian life. If the war has granted a fresh insight into the perplexing problems of the nervous system and into the various phases of the functions of consciousness, what opportunity will there be to utilize these gains when the same problems are presented in the reactions of the nervous system to the conflicts and stresses arising out of our post-war civilization? It appears that this sort of forehandedness has been more usual and prevalent in the minds of the medical profession as a whole, and particularly the neurologists, than has been the case in any war that we have any knowledge of. The literature of the present moment, so far as it is concerned with the medical problems of the war, is permeated with the thought of this effort to translate the experiences gained in the area of fighting into the conditions that are present in the every-day life of the average community. In an attempt to analyze the applications of knowledge to war conditions and to establish some kind of measurement of what was accomplished, this trend must be taken into account. If no post-war use of any measure that was found effective in the zone of fighting can be found, it is reasonable to conclude that its efficacy was transient and the gain illusive.

In the domain of the actual physiology of the nervous system and the anatomical phase of this question little can be said in the way of a definite increase in our knowledge. No new facts of great consequence came out of the many thousand cases of peripheral nerve wound, and no new physiological principle and no new note on the question of regeneration. There was some improvement in the technical handling of nerve wounds, and some more definite conceptions in respect to the manipulative treatment following surgical procedures. These touch more closely upon the questions of neuro-surgery, with which this paper has little concern.

Sensory Symptoms Following Severance

One phase of this topic deserves to be mentioned, however, as it points more readily to the type of illumination already mentioned. As these hundreds of cases of peripheral injuries came to be examined there was seen increasing evidence that the sensory symptoms following severance and those that developed during the various stages of healing became a matter of physiological inquiry. The curious phenomena of the sensory overlap and the diversity in the sensory return lead back to a series of pre-war investigations associated with the names of a group of English neurologists and physiologists. The war can be said to have directed attention to the practical utility of this work, and that it made for a great increase in the care with which the resulting symptoms were followed. Much of

this work is still uncompleted, and in the study of the residue of such cases still under medical supervision in America the physiological questions that cluster about a regenerating nerve may reach some measure of solution. The war has furnished a great many instances of this kind, and it can be expected that for many years such instances will be present for the intensive study that is required. In a similar fashion, the wounds of the spinal cord, of which there were many instances, furnish physiological opportunities. The functions of the spinal cord, especially its tendency to automaticity according to its primitive physiological and segmental structure, came in for much intensive study, and the Sherrington concepts received in the hands of at least one of his most distinguished students a full measure of testing.

The cerebral wounds and injuries resulting from shell and penetrating wounds of the skull gave a series of localizing experiments of extraordinary variety and complexity. Here, also, it is too soon to establish the permanency of the newly won facts. It will need all the experience that will be gained through the careful study of the re-education of the functions that have been temporarily lost, to determine if it is necessary to revise some of our previous points of view. There are now piling up in the note books of investigators the facts necessary for the final estimate of what utility all these cruel experiments may finally turn out to be. If, then, we review the whole aspect of the definite injuries of the nervous system, it is difficult to point out so far a series of definite gains to the various phases of the subject associated with the functions of the spinal cord or of the brain.

Utility of Pre-War Investigations

In the field of what has been called the functional diseases of the nervous system, among which war neuroses or shell shock takes its place, the war has been of great service in stimulating new lines of thought and giving unusual opportunity to test out and put into practical application the results of many years of pre-war study. It is this phase of neurology and its effect upon the demands that post-war conditions will undoubtedly furnish that the largest emphasis in a paper of this kind must be placed. The psychoneuroses, the civilian term given to that large group of abnormal nervous system reactions which show themselves under the various clinical pictures called neurasthenia, hysteria, or psychasthenia, come to the front in the war as specific war-born conditions, called shell shock, war neuroses, *nevrose de la guerre*, or *Kreig neurosen*. In civilian experience these conditions are termed functional, because they were obviously not the result of organic changes in the nervous system, but were functional deviations resulting either from some shock experienced or a series of unusual happenings associated with powerful emotional content. These were often congenitally predetermined, suggesting that the nervous system in such individuals was incapable of meeting the demands made through environmental conflicts. Towards the interpretation of these conditions various theories and notions had grown up and in a sense they had become crystallized almost into the rigidity of systems.

Response Is Essential Characteristic

The experiences of the war illuminated this subject from two important points of view: (1) It showed that any soldier under given circumstances would develop a neurosis and (2) it showed that the potential neurotic of civil life not only developed a war neurosis under less intense traumatic environment than the normal soldier but, also, that such an individual was less capable of cure, and thus belonged to the uncured residue that filled up so largely this class. The gain resulting from this experience lies largely in the first category, reflecting as it does the proposition that in the civilian neurosis generally, and in the war neurosis particularly, we are dealing with fundamental and primitive responses of the nervous system. This response is to be considered as an essential biological characteristic of the normal nervous system. It stands ready to spring into activity when the organic safety of man is in danger. The traumata of civil life awaken this dormant activity mainly in those who possess a less stable mechanism of adjustment, while the more severe traumata of warfare arouse this protective mechanism in any one.

In order to connect up this reaction with the normal response, it must be founded upon some very general and primitive characteristic of living things, and particularly must it be associated with some type of primitive response in man. This is to be found in primitive instincts. Two of these need only to be touched upon here: that of self-preservation and that of reproduction, or sex. The latter may be excluded in the present consideration as being included in the larger sense of the former term, or as showing itself in only very indirect reactions.

A normal nervous system under the stress and trauma of warfare, previously weakened by fatigue, hunger, and sleeplessness, in the presence of a sudden or unusual shock associated with extreme emotion, arouses the self-preservative in-

stinct into dynamic activity, automatic and uncontrollable. Induced by the primary emotion of fear, this activity protects the individual through the elaboration and stereotyping of sets of functionally abnormal responses which, conforming to certain clinical manifestations, give the picture which is called shell shock or war neurosis. These protect the individual from re-experiencing similar sets of traumata exactly as in the same way fatigue protects the individual from destroying his complete organism by fatal over-use.

Protective Quality of the Neuroses

This point of view is put into a dogmatic formula because it is only by so doing that we can suggest the illumination which it throws upon one of the least understood disease reactions of the nervous mechanism of mankind. The experience of the war based upon theoretical consideration, developed but not capable of direct application until put to actual test, leads now to the opportunity to build up a psychological mechanism of the neuroses from the standpoint of primitive instincts. The tracing of this line of thought during four years of war is an interesting story, but lack of time prevents the statement here of more than the briefest outline. The start, perhaps, was from the earliest Freudian conception of the protective quality of the neuroses,—its compromise aspect from the social point of view. The divorcing of this general reaction from the single factor of sex, a factor not seen in war, broke the thread of the Freudian process of thought and led to the seeking and finding of a more general principle. A group of English neurologists and psychiatrists,—Rivers, Meyers, MacDougall, Mott, and others,—each from his special standpoint, added to the general trend of thinking on this subject until at our own entrance into the war the foundation had been pretty well laid. A good deal of the further crystallization of this thought was due to the fact that the American Expeditionary Forces had an adequate machinery for the studying of the war neuroses in the establishment of a special hospital for these conditions in the forward area. This was called Base Hospital 117. There was formulated under conditions which in war-times must be called ideal a complete elaboration of the mechanism of the war neuroses. Here they were definitely established as clinical entities, typed and classified according to the notion just sketched. Here also were outlined certain ideas relative to the purpose and plan of the psychoses which in time may do for them what the neuroses of the war type promise to do for the civilian reaction of a like character. The experience of the war showed that there were episodes in apparently normal soldiers which took on many of the characteristics which are common in the psychoses of civilian life. A study of these conditions, owing to their crudeness and their acuteness of onset, permitted an insight into the intricate mechanisms of certain psychical states that may lead to pathways of inquiry of the most valuable kind.

A consideration of nervous and mental diseases, not merely as evidences of normal reactions themselves, but as reflections or as indications of the complexity of our social structures, leads directly to the larger view on this subject connoted in a phrase of today, mental hygiene. In the fighting area disease in general, and nervous disease especially, came to be viewed as events of military importance. A deficit in man power meant defeat, and a sick soldier was the unit of this defeat. Particularly true was this in a case of a soldier who, instead of being the victim of a disease in the ordinary conception of the term, or wounded in an evident way, was taken out of his place in the line because his nervous system as a whole had failed to adjust itself to military conditions. Physically he was sound and often rugged. He was a soldier in every way except that as a result of a shock his potential military capacity was incapable of translating itself into active fighting.

It follows that in any community under civilian conditions an individual who has failed to adjust himself to the demands of the civil conflict implied in the struggle for existence, and to the economic social stresses, through the compromise of a neurosis, must be regarded as a citizen-soldier for whose concern the community is responsible. Any one who falls a victim of a psychosis due to the same trend of causes takes his place in that community as a soldier who is prevented from carrying on his civic responsibility. For these maladjusted individuals the community must organize its best resources in order that return to duty may come about as easily and as promptly as possible.

Gains to Neurology Summarized

The resulting gain to neurology which has come out of the war is to be measured by facts of a new sort, by conceptions in regard to mechanism and by ways of thinking about previously established problems.

(1) There have evolved certain definitely observed facts as a result of the wholesale experience on the human nervous system. These facts have to do with the physiology of the peripheral nerves, the spinal cord, and the brain.

(2) There has been established a working basis for the understanding of the neuroses based upon

a psychology of instinct in which the primitive instinct of self-preservation and the emotion of fear have translated themselves into a protection for the individual under the guise of a disease picture.

Episode Reactions

(3) Certain groups of the psychoses are seen as episode reactions, closely related in origin and mechanism to the neuroses, but implying a more profound disturbance of consciousness. They tend to disappear as the need for them disappears.

(4) The handicapping of an individual by either of these conditions becomes of primary social significance, and the solution of the perplexing problem lies in the field of mental hygiene.

(5) A definite and incisive therapeutic method came out of the of war neuroses. Its efficacy can be measured by the large percentage of cured cases which were returned to active fighting conditions.

Object of Therapeutic Method

The central notion of therapeutic method consists in an attempt to influence a patient in such a way that he faces frankly and unafraid the conflict situation which has developed in his mind. He is taught that he must not depend upon instinctive processes of defense and protection, but must rely largely upon his ability to face his own problem and see it through. The effort to bring into active consciousness and expose to critical analysis of his normal mind the material automatically suppressed provides the means by which the individual can substitute a conscious for an unconscious defense.

A mere outline of this therapeutic idea scarcely can touch upon its future possibilities. Out of it should come a new therapeutic courage which, in the hands of trained and skillful neurologists, should create a therapeutic method which directly and incisively attacks the psycho-neurotic manifestations at their source.

Conclusion

My concluding word is this: After every war the world tends to pass through a phase reaction which is to be regarded as but the expression of the fatigue which grips a nation which has expended everything in the struggle.

The hard won gains of the war are often thrown away because of the apathy, weariness, intolerance, and fear of a tired people. Through such a period of transition it is to be hoped that the fruits of the war experience in neuropsychiatry may be translated, unweakened and vitally intensified, into all of its civilian phases.

DR. LANZA JOINS CLEVELAND FIRM AS MEDICAL DIRECTOR

Dr. Anthony J. Lanza, who heads industrial medical service.

DR. ANTHONY J. LANZA was born in New York in 1884. He was graduated in medicine from the George Washington University, Washington, D. C., in 1906, and became resident physician to the Casualty Hospital, Washington, D. C.

Dr. Lanza entered the United States Public Health Service in 1907. His service included one year in the United States Marine Hospital, San Francisco; he was then assigned to duty with the United States Coast Guard for two years and was boarding officer, San Francisco Bay, for a year and a half, after which time he was stationed at Fort Stanton, New Mexico Tuberculosis Sanitarium for two years and a half.

In 1918 he was assigned in charge of the office of industrial hygiene and medicine of the United States Public Health Service in Pittsburgh. This office moved to Washington, November, 1918, but had branches in Philadelphia, New York, Pittsburgh, Chicago, Cleveland, St. Louis and New Haven.

On the first of January, 1920, Dr. Lanza became medical director of the Hydraulic Pressed Steel Company, Cleveland, Ohio. This company, with two plants in East Cleveland, one in West Cleveland, and one in Canton, Ohio, plans a thorough and extensive medical service for the employees, including the industrial hygiene of the plant. The development of the complete medical service planned by this company under the direction of Dr. Lanza will be watched with interest.

A SHORTAGE of forty thousand trained nurses in the United States created a serious situation during the epidemic, and a campaign has been begun to enroll sixty thousand workers. While the epidemic was at its height women who had taken a short course offered in many cities, joined the corps of trained nurses and worked valiantly to check the spread of the scourge. Mobilization of all Red Cross nurses in the southern division was ordered. (Photos by Underwood & Underwood.)

THIS page illustrates some of the reasons why the epidemic of influenza this year failed to take so heavy a toll of human life as it did two years ago. Municipalities, aided by science, have put up a determined fight, with the result that the number of fatalities has been much smaller than when this plague first made its appearance. In the laboratories, white-capped and gowned men and women labor to perfect a serum which will achieve the desired results. This year three-fourths of the population of the world have been afflicted, but owing to a better understanding of how to treat the disease, the number of deaths has been materially reduced. In making experiments in the laboratory, white mice are used to test the serum. Funds are to be provided by Congress, if a resolution which has been introduced is given favorable consideration, to afford specific knowledge of preventive measures.

HEMIPLEGIA—SPONTANEOUS AND TRAUMATIC

WALTER D. WISE, M.D., F.A.C.S., Clinical Professor of Surgery, University of Maryland School of Medicine, and College of Physicians and Surgeons, Baltimore, Md.

NOT infrequently one sees a patient in coma with hemiplegia in whom there is a history or evidence of trauma. The task of the surgeon in this class of cases is to determine the nature and location of the lesion, and whether it is a cause of the trauma or a result; that is, whether the case presents an apoplexy in the usual sense, thrombosis or embolism, or intracranial damage as the result of injury. Typical cases are cited as follows:

Case 1.—A workman, age 40, engaged in repairing the top of a ear, fell to the ground and was rushed to the hospital in a deep coma. Examination showed no injury to the head, a few body bruises, and a complete hemiplegia. A diagnosis of apoplexy was confirmed at autopsy.

Case 2.—A painter, aged 30, fell from a scaffold (the scaffold did not fall) and was brought to the hospital unconscious with a hemiplegia. Examination revealed a slight abrasion and bruise on scalp. A diagnosis was made of probable apoplexy, but the motor region was explored. No evidence of extra or subdural injury was found.

Case 3.—C. M., age 38. He was seen by workmen sitting on his wagon seat apparently asleep, with head down, and leaning to one side. A red flag and shouts from the men did not prevent him from driving, or allowing his horse to go, into a ditch. He was thrown out and, when picked up, was unconscious and had a hemiplegia as noted by a well known doctor who happened along. He was sent to the hospital and examination showed paralysis of the right side of the face, and arm, and a partial paralysis of the leg. There were no bruises about his head or face. The blood pressure was 130. Urinalysis showed sugar. The next day he had regained consciousness and some use of the arm, with more use of the leg. There was no operation and in one week he was sufficiently improved to be moved to his home.

Other Types of Hemiplegia

Case 4.—*Localized edema.*—Man, age 19, injured by falling into the hold of a ship. Examination showed a slight contusion of the scalp in the right parietal region. He was unconscious for a few moments, then clear mentally, but became somewhat confused on the second day. He complained of headache and began to lose weight with remarkable rapidity. About the third day he began to lose the use of his left arm and leg. As soon as the paralysis was definitely established, he was operated upon. Exposure of the right motor region on the sixth day after injury showed no hemorrhage extra or subdural, but an exceedingly great amount of local edema within the pia-arachnoid. Drainage was made and reasonably prompt recovery took place. He began immediately to regain his lost weight, and gradually to recover motion in arm and leg.

Case 5.—*Subdural hemorrhage.*—R. R., age 28, injured in an automobile wreck. He lost consciousness immediately and when first seen, a very short time after the accident, no difference could be made out between the two sides. Later he became extremely restless and in thrashing about did not move the left arm or leg. Operation showed no extradural hemorrhage, but there were a large localized subdural hemorrhage and other free bleeding with a very red brain.

During the past few years the literature has contained many reports of alleged cases and of discussions concerning trauma as a causative factor in the production of apoplexy. It is universally admitted that blows on the head may cause compression or concussion and, by a laceration of brain tissue, excite immediate hemorrhage. Likewise, there is no question but that trauma may, and sometimes does, prove the exciting cause of apoplexy in individuals whose cerebral vessels are already in a condition of disease.

There are many who admit the possibility of arterial degeneration in vessels previously healthy, as a direct result of previous injury, but few can fully agree with Bollinger that all of his reported cases of "late traumatic apoplexy" were due solely to trauma.

The usual conditions which are responsible for the production of arterial changes, among which are advanced age, chronic heart, kidney and liver disease, typhoid fever, syphilis, and poisons, such as lead, alcohol, and tobacco, predispose to rupture and resulting hemorrhage.

Not only may the abnormal blood pressure, directly induced by the trauma, be sufficient to cause cerebral hemorrhage from these damaged vessels; but even in the more trivial injuries other conditions, such as excitement, fright, or anger, may have a similar effect.[1]

In the vast majority of cases the injury merely plays the part of an exciting cause in a person predisposed by reason of some vascular weakness due to alcoholism, nephritis, syphilis, or cardiac disease, as held by Eisendrath, Harbaugh, Mendel, Dana, and Golebiewski.

Stadelmann contends that in order to confirm the presence of true traumatic apoplexy it is necessary to prove the individual to have been perfectly healthy up to the time of the accident, especially not to have shown any vascular changes from lues, nephritis, alcoholism, or cardiac disease; and the trauma must not have happened to a person advanced in years on account of the arteriosclerosis always present in them.

The trauma must have had a certain seriousness, even if it was not followed by unconsciousness; and in cases occurring late after the original accident symptoms of vascular disease must have developed within a short period and under the observer's eyes. If years have elapsed after the injury, during which no observations of the arteries have been made, then it is impossible to establish a connection between the trauma and a subsequently occurring apoplexy.

1. Magruder: Traumatic Apoplexy.

In addition to the usual arterial changes, due to hardening of the vessel walls, miliary aneurysms may exist, which, when ruptured, may give rise to apoplectiform attacks.

As apoplexy has been known to follow any sudden exertion, such as lifting heavy weights or indulgence in violent exercise, and, likewise, from great mental strain, sneezing, coughing, overloading of the stomach and unusual indulgence in alcohol, these factors must be considered in connection with any case in which injury is alleged as the sole exciting cause of an attack.

Falls, excluding those which cause fractures, are more often the effect than the cause of sudden apoplexy, according to Thompson.

In the late traumatic apoplexies described by Bollinger, all of which ended fatally, there was an interval of days or weeks between the injury and the resulting hemorrhage. He considers the apoplexy as partly due to the change in the vessel walls, which occurs as the direct result of the original injury, and partly to the yellow softening of the surrounding brain tissue, which follows, meantime depriving the vessels of their nutrition.

Langerhaus and Israel disagree with Bollinger, and, after a critical study of his cases and others, are unwilling to accept them as the result of the initial trauma.

Wimmer claims that if, at autopsy, necrosis and hemorrhages are found in the ventricles, or there exist other symptoms of a direct cerebral contusion, or paralysis of muscles pointing to a localization, the diagnosis of a traumatic apoplexy, with some degree of safety, can then be made.

Stadelmann and Israel demand that, in true traumatic apoplexy, death must have appeared after a paralytic attack; must have ensued some time after the trauma; autopsy must not expose a number of small hemorrhages, but must show one or more large ones which would have been sufficient to have caused the paralytic attack.

At autopsy, in order to judge whether or not a hemorrhage was spontaneous or resulted through trauma, certain conditions must obtain. Spontaneous hemorrhages are always central,—spread from the interior to the exterior, and, usually, through their resulting paralyses, point to their exact location. In traumatic central apoplexies meningeal hemorrhages are always likewise present.

Mendel, after an extensive study of the reported cases, found that the time elapsing between the appearance of the apoplexy and the initial trauma varies between four days and nine months, and he contends further that, if the hemorrhage should occur after a longer time than nine months, its connection with trauma is quite unlikely. In the cases ascribed to trauma an interval of from one to six weeks has usually elapsed before the vessels rupture, and during this time, no doubt, the necessary vascular changes are progressing.

For a diagnosis of traumatic apoplexy, clinically and pathologically, it is necessary that the patient should have previously been in perfect health; should show no signs of arteriosclerosis, nor have suffered from lues, cardiac diseases or alcoholism, for in the presence of these conditions the chances for the occurrence of cerebral hemorrhages are so great that it is impossible to give to a preceding trauma any positive value as a casual factor (Bryant and Bruns, Bailey, Harbaugh, Golebiewski).

Paralysis in Nephritis

A patient suffering with Bright's disease may be stricken with a convulsion or coma and develop a mono- or hemiplegia and if the seizure is accompanied by a fall, the element of trauma as a cause of the paralysis may be hard to exclude. The paralyses occurring in uremia are usually due to localized cerebral edema or possibly local anemia. There is no hemorrhage. Of course, a true apoplexy may occur in a nephritic.

Spinal Hemiplegia

Brown-Séquard's paralysis due to injury, if associated with cerebral trauma, would produce a confusing picture. If time and conditions permitted a reasonably thorough examination, the diagnosis should be clear.

Of this condition Osler says:

> The motor symptoms which follow lesions confined to one half of the cross section of the spinal cord follow the same rules as those given for transverse lesions except that they are confined to one side of the body; that is, they are on the same side as the lesion.
>
> The sensory symptoms are peculiar. On the side corresponding with the disease, the paralyzed side, there is anesthesia corresponding to the segment of the cord involved; above this there is a narrow zone of hyperesthesia, but below this there is no diminution in the senses of touch, pain, or temperature; Indeed, there is often hyperesthesia. The muscular sense, however, is impaired. On the side opposite to the lesion there may be complete loss of the sense of touch, pain, and temperature; or it may only involve one or two of these, pain and temperature usually being associated.
>
> This combination of symptoms was first recognized by Brown-Séquard after whom it has been named. It is common in syphilitic diseases of the cord, and may follow tumors, stab wounds, fracture, and caries of the spine; and it is not infrequently associated with syringomyelia and hemorrhages into the cord.
>
> The explanation of the disturbance in sensation is not satisfactory, and can not be until our knowledge of the

paths of sensory conduction is more accurate. These cases have convinced most clinicians that in man the paths for touch, pain, and temperature cross in the middle line soon after entering the spinal cord, and proceed toward the brain in the opposite side; while those for muscular sense remain in the dorsal columns of the same side. We have seen that anatomy lends some support to this view, and this is the explanation that is usually given. The experiments on animals have thrown some doubt on this view, especially those of Mott on monkeys, which seem to indicate that the sensory paths for the most part remain on the same side of the cord.

Cerebral tumors and abscesses giving rise to pressure symptoms, and edema resulting from these conditions would not likely come within the subject under discussion.

Destruction of the motor cortex as by bullet wounds, and pressure and paralysis by depressed fractures are usually easily diagnosed.

Hemiplegia may be due to apoplexy, thrombosis or embolism leading to softening, cortical hemorrhage, extradural and subdural hemorrhage, depressed fractures, destruction of motor cortex, tumors, abscesses, nephritis, local edema, hemorrhagic pachymeningitis (usually in the insane), hysteria, and disease or injury of the spinal cord, —Brown-Séquard paralysis.

Hemiplegia may be the result of a lesion in (1) the motor cortex; (2) the pyramidal fibers in the *corona radiata* and in the internal capsule; (3) the cerebral peduncle; or (4) the *pons varolii.*

The hemiplegia may be (1) complete,—meaning paralysis or disturbance of motor control of face, tongue, arm or leg; (2) partial,—meaning a disturbance of motor control of any two or more of these parts; (3) crossed,—meaning a paralysis in which there is loss of function in a cerebral nerve on one side with loss of power or sensation on the opposite side of the body; or (4) false crossed or false alternate, in which a cerebral nerve itself is damaged and there is also damage to some part of the motor tract,—as in a fracture of the base of the skull with injury to the facial nerve, giving rise to an extradural hemorrhage and paralysis of the opposite side of the body or some part of it.

There is, as a rule, no reason to confuse typical cases of apoplexy, embolism, thrombosis, or spontaneous hemorrhage in tumors with trauma, and in a large percentage of traumatic cases the symptoms and signs are plainly the result of injury. There is, however, a small group in which it is most difficult or impossible to make a differential diagnosis. Frequently there is great urgency to make a decision; no history can be obtained from the individual or witnesses, and there is not time for a prolonged investigation.

If there were witnesses, their account of the fall, accident, or seizure is of the greatest importance; the evidence of persons seeing the patient a short time before, or a short time after the accident, may be of great value.

The presence or absence of the results of trauma, such as contusions of the scalp, bleeding from the nose, ear, or mouth, should have great weight in forming an opinion.

If there is a history of a fall without apparent cause, particularly in an elderly individual with arteriosclerosis, followed by immediate complete hemiplegia and no evidence of severe trauma to the head, it is probably apoplexy. The hemiplegia being incomplete does not, however, mean the lesion is not in the internal capsule, as this whole structure is not necessarily involved in the apoplexy that occurs so frequently from hemorrhage in that region.

A blow on the head, momentary unconsciousness, a lucid interval, slowly developing paralysis beginning with the face, then the arm, then the leg, is almost surely an extradural clot; but examples of a complete hemiplegia from this cause are not often encountered.

Cushing reports that "instances of actual hemiplegia from an extradural hemorrhage have been recorded, but they must be rare, since the centers for the lower extremity lie so far away from the primary point at which an extravasation is likely to arise that a clot large enough to implicate the upper ridge of the hemisphere would in all probability either lead to such deep coma that symptoms of hemiplegia could not be appreciated or would cause death before they were apparent."

A subdural clot producing a hemiplegia is also rare, but does occur; it is usually associated with unmistakable evidences of severe injury and unconsciousness; the paralysis usually becomes generalized, and there is frequently disturbance of the medullary centers.

Uremia very rarely develops under conditions to cause it to be confused with trauma, but, if it should, urinalysis plus the eye grounds should help make the diagnosis.

The absence of albuminuric retinitis does not preclude the condition being uremia, neither does the absences of choked disc preclude its being intracranial trauma. Trauma may cause an edema of the brain or local increase of cerebrospinal fluid in the arachnopial membrane sufficient to cause a hemiplegia. This may be limited or become generalized Clinically, it may resemble middle meningeal hemorrhage but the unconsciousness and coma are less marked and are not steadily progressive. Headache is very severe and on percussion there is marked tenderness which may be elicited even after patient has ceased to answer questions or take notice of his surroundings.

THE REPAIR OF BONE

JUST what takes place in the repair of bone and what structures enter into the process, are questions which have long remained unanswered. Macewen, in an excellent article in 1912, did much to clarify our contradictory conceptions, and W. E. Gallie and D. E. Robertson[1] of Toronto, Can., have recently published an exhaustive treatise on the repair of bone. We feel it well worth quoting at length from this article.

The authors first attempt to state the rôle played by the periosteum. They believe with Macewen that the periosteum is a limiting membrane, whose chief function probably is to carry the blood supply to the bone. Except at the epiphysis, the periosteum is loosely attached through the medium of a delicate areolar tissue. In the interstices of this areolar tissue are many osteoblasts.

When the periosteum is gently reflected, most of this areolar tissue clings to the bone. If a sharp instrument is used, much of this structure can be lifted with the periosteum and, as a result, many osteoblasts will be raised along with it. After the subperiosteal resection of bone, new bone will grow from the periosteum. The authors resected a length of bone subperiosteally; they split this resected bone in half, boiled one of the pieces for five minutes, and then replaced both fragments. In the case of the unboiled graft, bone appeared on the surface; but in the case of the boiled bone no such changes occurred, demonstrating rather clearly that the bone itself was the origin of the new bone growth, not the periosteum.

The bony growth under the periosteum in osteomyelitis, or in subperiosteal hemorrhage, as in infantile scurvy, is readily explained by the great proliferation of osteoblasts due to the inflammatory changes, so that now when the periosteum is stripped by the pus or the hemorrhage, many osteoblasts will be lifted with it.

In fractures the subperiosteal osteoblasts are very active; but Macewen has shown that if a fracture is produced in the shaft of a bone after the removal of the periosteum from that area, not only does the ensheathing callus develop but its quantity is actually increased. To state that the osteoblasts situated in the areolar tissue constitute a part of the periosteum will lead to erroneous ideas on the part of the surgeon that the periosteum, as he understands it, can be depended upon for osteogenesis. Transplantation of the periosteum with the graft is not essential. In amputations the authors believe that the simple method of cutting the periosteum at the same level as the bone is entirely satisfactory.

When a piece of bone has been cut free from its circulation and transplanted into some other

1. Gallie, W. E., and Robertson, D. E.: The Repair of Bone, Brit. Jour. of Surg., 1919, vii, No. 26.

position in the same animal, if it is freely bathed in lymph, those cells on its surface and in the open mouth of the haversian canals will live and proliferate, while those situated deeper in the lacunae will die. After the second week it will be noted that the proliferating cells have begun to absorb the bone. At the same time, but to a much less extent, there is found to be bone production. The circulation is reestablished throughout the graft by ingrowth of new blood vessels.

Along with these blood vessels the osteoblasts also pass into the interior of the bone, and rapidly continue the process of absorption. During the first two months the process of absorption goes on much more rapidly than replacement, so that by the end of this period the dense bone of the graft has become greatly rarified. If the graft is not subjected to any strain, and has no definite part to play in the function of the area into which it was implanted, the absorptive process continues in advance of the replacement and gradually the new bone also disappears and its place is taken by an ordinary scar.

Transplantation of bone in skeletal gaps produces changes similar to those produced by transplantation elsewhere, but the process of proliferation proceeds more rapidly. Following the destruction of circulation, all the bone of the graft dies and any changes or signs of life that may appear later result from the growth into it of osteoblasts from the neighboring living bone. The cells of the living bone respond to the stimulus of the dead bone, rapid proliferation occurs, and the graft soon becomes securely united by trabeculae of new bone. Active absorption by the osteoblasts commences and as the circulation is reestablished the osteoblasts spread throughout the whole graft. At the same time, new bone is laid down, so that the absorbed bone is replaced by a fine mesh of new cancellous tissue which is gradually changed to the density that the physiological function of the area requires.

When the graft is inserted as a bridge in ununited fractures, it is found that the bone proliferation at the edges of the graft, due to the outpouring of osteoblasts from the ends of the fractured shaft, is very marked. The rarification in the center is pronounced as in other instances.

This therefore demonstrates the necessity of using grafts of considerable strength, in order that their integrity be retained during the period of osteoporosis. When boiled bone or heterogeneous grafts, which when implanted into muscle are not viable, are used, it is found that the proliferation at the edges, due to the outgrowth of osteoblasts from the shafts of the bone, extend never more than one-half inch. For short defects, therefore, boiled bone, or heterogeneous grafts would be very satisfactory. For longer gaps, autogeneous grafts are necessary, unless, as the authors surmise, homogeneous grafts can be used in a recipient whose serum would be compatible to the cells of the graft. Plates made from boiled bone not only hold the fragments in good position but, because of the process of osteoclysis and osteogenesis, are finally absorbed and replaced by living bone.

The authors close their article with a word of warning against sepsis. Sepsis must always be feared in gunshot fractures and at least four to six months should be allowed to elapse after apparent healing before operation on ununited fractures should be considered, and then only after careful study of the case with the assistance of x-ray fails to show any signs of infection.

W. E. Gallie,[2] in another article, mentions the successful lengthening of an amputation stump by making a sliding graft from the remaining part of the femur, pushing this graft forward and holding it in place with screws of boiled bone. Six months later an x-ray picture showed that the bone from which the graft had been taken had been restored to its former density, while the graft itself had also thickened.

Albee and Morrison[3] in a recent article say: "Investigations made regarding the difference in osteogenetic power of the periosteum, by scraping the outer surface of the bone with a sharp instrument or by separation through the easier line of cleavage with a blunt instrument, show that in the first place the complete periosteum was obtained and found to be a very potent osteogenetic element, whereas in the second case the osteogenetic activity was found to be localized only in the spots where portions of the cambium layer happened to come away with the so-called 'limiting membrane' of Macewen." In the same article the authors advance evidence to refute arguments that x-ray in dosages as used for taking control pictures in fracture work can have any retarding effect on the process of osteogenesis, and certainly can not account for non-union.

Albee and Morrison[4] have found that the injection of a 5 per cent solution of triple calcium phosphate in distilled water in a gap made by the resection of a small portion of the shaft of the radius of a hare, resulted in a much more rapid bone growth and union than appeared in the control animals. In no case did the solution act as a local irritant or a systemic toxin. The authors

GASTRIC ULCER

A VERY interesting article by Crohn and Reiss[1] is based on the careful study of thirty-four gastric cases. In five a gastric ulcer was later demonstrated at operation; in twenty-one, ulcer was the clinical diagnosis; and in eight the diagnosis was that of functional disturbance. All present used methods were employed in studying the cases, but the Rehfuss fractional test meal was especially utilized to follow gastric secretion and hypersecretion, gastric acidity and motility. Sippy and Lenhartz diets, and modifications of these, combined with frequent small doses of antacid, were given.

Although 73.5 per cent of these cases left the hospital symptom free, in only 38 per cent was the acidity reduced. Twenty cases in the series showed hypersecretion and in only nine cases, 45 per cent, did the amount of gastric secretion become normal. Thirteen cases showed delayed motility, and in eleven of these the motility returned to normal. The two cases in which this did not occur were unimproved.

There is, therefore, a marked disproportion between clinical improvement and improvement in hyperacidity, hypersecretion, and delayed motility of the stomach. The authors elaborate upon this and frankly state that their studies do not explain why various types of "ulcer diet" alleviate ulcer symptoms. They do not consider the question of cure by medical means in this series of cases; in fact, five cases were subsequently operated and gastric ulcers found.

One is impressed with the persistence of hyperacidity and the loss of gastric symptoms. Hyperacidity has been blamed on insufficient evidence, or on no evidence at all, for almost every gastric disease which occurs. It has especially been supposed to be the main cause of ulcer pain. It is a great satisfaction to find that in this article nothing is taken for granted and only facts are presented. This excellent article suggests that it would be extremely interesting, to say the least, to find out if the streptococci which are found in gastric ulcers are influenced by the degree of gastric acidity. More investigation of these streptococci is needed.

In this connection is to be noted the recent communication by Ivy[2] on "Studies on Gastric Ulcer." This article is the fifty-second contribution to the "Physiology of the Stomach" from Carlson's laboratory. It is in two parts, one devoted to experimental production of chronic gastric ulcer in dogs, and the other to the motility and emptying time of the stomach in acute experimental gastric or duodenal ulcer.

An excellent review of the literature of experimental chronic gastric ulcer is given. The stomachs of 900 dogs, which were used for class physiological experiments and can be considered normal dogs, were inspected for gastric lesions and found practically free. Only one stomach, that of an old, emaciated dog, showed an ulcer, findings which verify previous reports of rarity of gastric lesions in dogs.

Ivy failed to produce chronic ulcers until one dog developed this type of lesion after contracting distemper following an abrasion of the pyloric mucosa and feeding cultures of *Streptococcus viridans* with his food. Other dogs, which remained healthy when submitted to this procedure, did not develop chronic ulcers. Several other dogs with distemper or with cachexia from ligated pancreatic duct did develop chronic ulcers subsequent to the above experimental conditions. None of these chronic gastric ulcer dogs had free acid in their gastric juice. The same type of *Streptococcus* which was fed was recovered from the ulcers. Ivy believes, therefore, that it is not hyperacidity which contributes to gastric ulcer formation, but hypo-acidity, which allows bacteria to live and multiply in the stomach. He believes that some functional or systemic condition which causes gastric hypo-acidity, and also lessened general and local gastric resistance, is at present the most probable explanation of the etiology of chronic gastric ulcer. In this connection it must be remembered that the etiological relationship of bacteria to gastric ulcer has not been decisively proved.

In the second part of the article, Ivy shows that pyloric or duodenal ulcer in dogs causes delay in emptying time and, after twenty-four hours starvation, increases motility. Ulcer in the fundic position has no such effect. This corresponds to clinical observation.

Separation of the stomach from its extrinsic nerves—the vagi, splanchnics, and celiac plexus—only lessens the above effects of the ulcers. This shows that the fundamental cause of these effects is intrinsic but is enhanced by the extrinsic nervous mechanism.

In a review of Carlson's book on hunger, in the January, 1920, issue of MODERN MEDICINE, we pointed out the value of modern physiological

methods in the clinical study of cases of gastric disease. It is interesting that in Carlson's laboratory experimental gastric disease is being studied in this manner, and it is hoped that clinicians will see the value of these methods.

MEASLES AND EXPERIMENTAL INOCULATION

THE average layman when he thinks of measles is prone to place it in the category of those mild ailments, like the common cold, which seem sent more to plague us during the period of our childhood than to have any more serious significance. Indeed, one still meets the parent—fortunately much less frequently than formerly—who takes the view that the young child will get measles some day anyway, "so he might as well have it now and get it over with." It is unfortunate that most of these laymen remain ignorant of the fact that hundreds and even thousands of children annually lose their lives from this cause, but the havoc wrought by measles in some of the army camps has received a somewhat wider publicity. The many complications and relatively high mortality among a group of physically perfect men was the occasion of deep concern to the government and furnished the stimulus for a number of fruitful pieces of research.

One interesting communication is that of Sellards,[1] who attempted to produce measles in susceptible human beings by inoculating them with blood taken from patients in the early stages of the disease. The subjects of the experiment were all soldiers who had volunteered for the purpose, but neither the eight susceptible individuals nor the two control immunes could be infected in this manner. (It will be remembered in this connection that Hektoen[2] has reported two successful inoculations on humans, while Anderson and Goldberger[3] apparently succeeded in transmitting the disease to monkeys by means of similar inoculation.) Some weeks after the above experiments, Sellards exposed two of the inoculated susceptibles to an early case of measles, and even applied some of the buccal and nasal secretions of the measles patient to the mouth, nose, throat, and eyes of the subjects, again failing to produce the disease.

The question which naturally arises is whether these individuals, giving no history of measles, in spite of the most careful search of their past lives, were really susceptible to the disease, and whether immunity was conferred by these inoculations. If it be possible to produce an active immunity to measles in this manner, a point which awaits the confirmation of further experiment, then the way has been opened for the perfection of a method which should result in the saving of hundreds of lives annually claimed by this disease.

Experimentation on human beings is only justifiable under certain rather extraordinary circumstances, but after all, affords information which can be obtained in no other way. Volunteers who go to the front for science have a right to expect every safeguard which can be thrown around them without jeopardizing the terms of the experiment. Thus, in the present instance, not only were physically fit men chosen, but every precaution was taken to lessen the chances of a serious outcome should these men develop measles:—before the experiment, tonsils, sinuses, middle ear were examined, latent tuberculosis eliminated as far as possible, and cultures to show the subject free from hemolytic streptococci, pneumococci, meningococci, diphtheria, and Pfeiffer bacilli. Careful nursing and rigid isolation were insisted upon as a matter of course in protecting the volunteers from intercurrent infections, as well as from spontaneous infection with measles.

TOXINS AND ANTITOXINS OF BACILLUS DYSENTERIAE SHIGA

THE toxins and antitoxins of *Bacillus dysenteriae Shiga* form the subject of a recent report by Olitsky and Kligler.[1] They note that the toxin of the Shiga dysentery bacillus has been studied by a number of bacteriologists but that no agreement has been reached as to its precise nature. Some investigators have regarded this toxin as an endotoxin, and others as exotoxin.

Olitsky and Kligler isolated both an endotoxin and an exotoxin, the two toxins physiologically and biologically distinct. When injected intravenously into rabbits the exotoxin causes lesions in the central nervous system, such as hemorrhages and small areas of necrosis, and, also, causes paralysis in the animal. It does not produce any lesions of the intestinal tract. The endotoxin, on the other hand, causes edema, necroses, hemorrhages, and ulcerations in the intestines, but no lesion of the central nervous system. Anti-endotoxin serum was prepared, and was found to neutralize the endotoxin, but not the exotoxin. An anti-exotoxin serum was prepared, and this had a similar specific action on the exotoxin.

1. Olitsky, Peter K., and Kligler, I. J.: Toxins and Antitoxins of Bacillus Dysenteriae Shiga, Jour. Exper. Med., 1920, xxxi, 19.

They obtained from horses a potent serum which contained both anti-endotoxic and anti-exotoxic antibodies.

This investigation appears to be very important, for it demonstrates an anti-dysenteric serum which possesses neutralizing properties for both types of dysenteric toxin. It is probable that some of the poor results obtained with anti-dysenteric serum were due to the fact that immune bodies for one or the other of the two toxins has been absent.

It is to be hoped that commercial sera of the sort prepared by Olitsky and Kligler will soon be available for general use. It will be necessary, however, to find out whether the toxins of the other types of dysentery bacilli correspond to those found for the Shiga type. It also will be important to treat cases of summer diarrhea caused by dysentery bacilli with this new type of serum.

STANDARDIZING BACTERIAL SUSPENSIONS

IN the same number of the *Journal of Experimental Medicine*, Frederick L. Gates[2] publishes a method of standardizing bacterial suspensions. He has devised a simple instrument for determining the number of bacteria present in a cubic centimeter of a bacterial suspension. This instrument has to be standardized each time against a suspension of a given organism and, therefore, should be of value in making bacterial counts of vaccines containing only one organism. It apparently cannot be used in making counts when the type of organism is unknown, or where several organisms are present in an unknown proportion, as in the autogenous vaccines. In these cases we must still rely on the present methods for counting vaccines.

COMPLEMENT FIXATION IN DIAGNOSIS OF TUBERCULOSIS

THE conclusion is reached by W. H. Moursund[3] that "the complement fixation test for tuberculosis as described in his article is of no value as a diagnostic or prognostic aid."

It should be noted that the antigen used was Petroff's. This antigen is quite different from that devised by Miller. Miller has reported much better results with his antigen, than Moursund obtained. A number of articles, however, have appeared in the last several years, in which a variety of tuberculosis antigens were used. The general opinion of the various workers, with the exception of Miller, seems to be about the same as the conclusion arrived at by Moursund.

STUDIES ON ROCKY MOUNTAIN SPOTTED FEVER

A VERY comprehensive article by F. Burt Wolbach[4] has recently been published on Rocky Mountain spotted fever which includes an excellent historical review of the subject. There is also a complete description of the disease. Nothing especially new is brought out, but most of the pioneer work of Ricketts, and others, is verified and amplified.

The minute intracellular coccoid organism originally described by Ricketts was found also by Wolbach. This was found intracellularly, especially in endothelial cells at the region of the blood vessel lesions of the disease. Ricketts proved that the virus of the disease was not filterable through Berkefeld filters. Wolbach did not repeat this work, but made numerous and varied attempts at cultivating the organism, but was unsuccessful. There are many excellent illustrations and the article is well worth reading by anyone interested in the disease. W. T.

THROMBOPLASTIC AGENTS

ARTICLES by P. J. Hanzlik[5 6 7 8] and several different collaborators in recent issues of the *Journal of Pharmacology and Experimental Therapeutics*, on the subject of thromboplastic agents, report investigations on the subjects of blood-clotting efficiency of thromboplastic agents in vitro, of hemostatic properties of these agents under different conditions, and anaphylactoid phenomena from these agents.

They found thromboplastin and kephalin more efficient in vitro than coagulen, coagulose, and hemostatic serum. Both kephalin and thromboplastin lose their thromboplastic activity on standing. The hemostatic effects of these agents tested on animals in general tend to agree with their action in vitro. This could not be tested, however, as accurately as in the vitro experiments.

The thromboplastic agents rich in protein [Thromboplastin-Squibb and Armour and Hemo-

static Serum] produced anaphylactoid symptoms in guinea pigs when injected subcutaneously and intravenously, and caused death when large doses were injected intravenously. The injurious effect was found to be caused only in part by the preservative trikresol. Kephalin appears to be comparatively harmless as compared with the other thromboplastic agents studied. The authors note that the thromboplastin (Squibb) used was the ordinary variety, and not that marked "Thromboplastin Hypodermic." They cannot state whether the "Hypodermic" produces the same effects as the ordinary thromboplastin.

It is important to have learned that a certain amount of danger attends the use of these agents. It may be pointed out that the use of whole human blood, locally, or as a transfusion, is not attended by danger and probably is more efficient than such thromboplastic agents as those studied by these workers. W. T.

PNEUMOPERITONEUM

THIS new field of work bids fair to outstrip almost every other Roentgen procedure. Judged on its merits, its possibilities promise to enable roentgenologists with exactness to come to hitherto impossible conclusions in the diagnosis of abdominal pathology. This work was first done by a German, Prof. G. Rautenberg, in 1914. Two men in the United States, Stewart of New York, and Dr. B. Orndoff of Chicago, conducted independent investigations along this line. Dr. Stewart reported his work in a paper read at Saratoga Springs in the fall of 1919, before the American Roentgen Society. Dr. B. Orndoff reported his work at the meeting of the Western Roentgen Ray Society in Chicago, December 12, 1919.

As all Roentgen workers know, gas anywhere within the tissues renders more visible those structures lying under or above it. This accounts for the easy observation of the chest contents and the outlining of soft structures in the abdomen when gas is present in the gastro-intestinal tract. Even pelvic bones of heavy individuals may be easily outlined over the areas of gas in the intestines.

It is this principle which is utilized in pneumoperitoneum. The gas used includes filtered and washed air, carbon dioxid, oxygen, and nitrogen, each of them having a different time for absorption varying from thirty minutes to a week or ten days. The method of introduction into the peritoneal cavity is by means of a trocar attached to a rubber tubing connected directly to a gas tank. Interposed in this gas line there is an equilibrium gage, and a cotton filter to take out the moisture accumulated by the gas passing through the washing chamber. The trocar is pushed through the abdominal wall as is done in any paracentesis.

The amount of gas injected does not seem important, being determined by the tenseness of the abdominal wall. No serious effects are reported to have followed inflation of the peritoneal cavity. The patient is examined in both the upright and recumbent postures while the gas is being introduced, and afterward. Sometimes a slight feeling of pain and discomfort is felt under both scapulae and in the shoulders when the patient assumes the upright posture, but with a change to the recumbent position these symptoms are immediately relieved. The patient is best examined under the fluoroscope, where the patient can be rotated in any desired position.

As the gas enters the abdomen it is visualized as a bright spot on the fluoroscopic screen. Naturally it will rise to the highest possible level until it fills the entire peritoneal cavity. By rotating the patient, the subphrenic spaces can be made to fill and are distinctly seen; the diaphragm, instead of offering a tremendous resistance to the rays, as it usually does, now only shows as a thin curved line.

The liver falls away from its close relation to the peritoneum unless held down by adhesions in which event these may be clearly seen. In a similar manner the spleen and kidneys are also visualized, and any deviation from the normal easily demonstrated. By placing the patient in the Trendelenburg position the gas fills the pelvis and outlines the pelvic contents; the uterus, ovaries, and tubes become visible, especially if pathological. The possible sources of danger such as puncturing an artery, vein, nerve, or even a loop of intestine seem to exist in theory only, so far not a single case of punctured intestine having been reported. Another source of danger that has been discussed is that of infection which, however, should not be a cause of alarm, for the same aseptic precautions are observed as in any paracentesis or spinal puncture.

There are certain indications for this abdominal work. It should not be used in every case as a routine measure, but rather after all other means have failed, or in obscure cases with no definite findings.

A word of warning must be conveyed. In the proper hands it is a safe and valuable procedure, —an adjunct to the interpretation of abdominal pathology. It should be used only where it is possible to observe all the rules of asepsis and antisepsis. In the hands of those who are skilled in this work and who can correctly interpret the

findings, the procedure is full of possibilities. Care must be taken that a note of conservatism should echo throughout this entire work in order that so valuable a method should not be brought into the discard by its abuse in unskilled hands.

It is a marked step forward from the comparatively recent advent of the static machine, with its limited scope, to a technic which permits detection of peritoneal adhesions by means of pneumoperitoneum. ROBERT A. ARENS, M.D.

THE AMERICAN JOURNAL OF PHYSIOLOGY

SELDOM has an issue of a magazine been as rich in medical contribution as is the October issue of the *American Journal of Physiology*. The question of acidosis, that very complicated and yet important subject which deals with the normal and abnormal reaction of the human body, is discussed in two articles by Asada. The first[1] of these articles deals with acidosis during starvation. That there is a lowering of the alkali reserve during starvation is corroborated by these studies. The author, furthermore, finds a regular curve manifesting itself during starvation.

The second contribution[2] to acidosis is on the relation of acidosis to vital staining. The author finds that vital staining can not be accomplished by a single intravenous or intraperitoneal injection of lithium carmin in subtoxic doses in a healthy animal. If, however, an acidosis be first established, a single injection of the dye will give a satisfactory stain. In animals which have been vitally stained, an actual decrease in plasma bicarbonate occurs.

The author, therefore, draws the conclusion that it is incorrect to predicate the existence of specific stain-taking substances or granula in the cells; rather, vital staining with lithium carmin is due to the development of an acidosis which so alters the function of the body cells that the dye diffusing it is deposited in granula. This deposition corresponds to the precipitation from collodial solution of the dye when the normally alkaline solution is made acid in vitro.

In addition to the above mentioned contributions on acidosis, the same issue contains two important papers on the subject of catalase. Possibly the latest fashion in medical literature is to discuss the subject of enzymes. No enzyme, however, has attracted as much attention as the innocent catalase which, put in common terms, has the power of liberating oxygen when blood cells come in contact with hydrogen peroxid. Burge, of the University of Illinois, has seen the power of catalase in many diseases afflicting the human body. He is being followed by a host of other workers who consider catalase a very important enzyme disturbing the human elements. Burge even went one step further in suggesting therapeutic measures from the standpoint of catalase action. Frank Becht, of the Northwestern University Medical School, however, saw no marvel in catalase and considered it only a minor factor in human economy as well as in human diseases. He even went so far as to contradict all of Burge's work.

Far be it from us to undertake to decide between these two, but we would only like to call attention to the two articles on catalase in this issue of the *American Journal of Physiology*, one by Burge[3] continuing to attach extraordinary importance to the action of catalase, and the other article by Reimann and Becker[4] criticising the methods used for determination of catalase and seeing no special rôle played by catalase during anesthesia. To say the least these reports make interesting reading and are important from a historical standpoint, for it is well known all important matters have their pro and con at some stage of their development.

Besides the contributions already mentioned, there are many others of great interest to the scientist, and to the practitioner, that are contained in the pages of the October issue. Such, for instance, is the work on traumatic shock from Erlanger's laboratory,[5,6] and the work on "The Control of the Pylorus" from Carlson's laboratory.[7] The contributions are fundamental and make good reading matter.

THE HIGH COST OF SICKNESS

The cost of preventable sickness should not be charged to the high cost of living, according to William Fellows Morgan, trustee of the United Hospital Fund, of New York City. It is the business of everyone, he says, to see that the yearly cost of being sick is reduced. The $54,000,000 required annually in New York for the care of the sick but adds to the burden of the people. Sickness also eliminates productive labor. Such social and economic waste should not be permitted to continue.

Prevention of sickness where possible would to that extent make available the hospital service which is at present so inadequate for the demands made upon it. Mr. Morgan estimates that present institutions provide care for only about one in ten needing it.

THE HEART IN ACUTE INFECTIOUS DISEASES—COLLECTIVE ABSTRACT

By WAYNE A. RUPE, M.D., Washington University Medical School, St. Louis, Mo.

IN reviewing comparatively recent literature on the heart in infectious diseases with especial reference to the acute specific infections in childhood, it seems that very little extensive work has been accomplished. The impetus given to investigation of such nature by the growing use of the electrocardiograph was effectively curtailed by the war. Increased interest in this problem is demonstrated at the present, however, in view of which fact this attempt to collect the most valuable recent contributions is made.

Symptoms of Myocardial Weakness

Chapin[1] has discussed the heart in infectious diseases in a general way. He points out the fact that the heart, and in fact the whole circulatory apparatus, is more or less profoundly affected by an increase in temperature, and that the reaction varies somewhat in different cases according to the nature of the agent producing the fever. In general, however, the clinical symptoms and signs of myocardial weakness are similar in all specific infections in the course of which such manifestations are wont to occur. One of the most characteristic of such symptoms is irregularity of the heart beat. Others are variations in the size of the heart and alterations in the character of the heart sounds. Murmurs of a functional nature, frequently the direct result of dilatation, are often observed. He says that physiological arythmias are usually abolished during excitation of the heart by fever except in those cases, such as tuberculous meningitis, in which central vagus stimulation is a prominent feature.

Nobécourt[2] also discusses the syndrome of myocardial insufficiency occurring as a complication of acute specific infections. Cases in which such a condition develops readily group themselves either among (1) those in which physical signs of myocardial weakness are present, but which are unaccompanied by subjective symptoms, or (2) among those in which develop marked symptoms referable to cardiac embarrassment.

(1) Cases which fall into the former classification usually present one or more of a distinct group of features. Temporary or persistent dilatation is frequent; if temporary, it is subject to recurrence. Variations of rhythm are frequently the only phenomena presented. Tachycardia or bradycardia are not rarely observed; the latter occurs with especial frequence during the convalescent period of diphtheria, pneumonia, and typhoid fever, and is often accompanied by sinus arythmia. Usually the heart sounds lack muscular quality. The pulmonary second sound is frequently accentuated. These signs are detected only on detailed physical examination and to such features the term latent myocardial syndrome is applied.

(2) In the second group, the patient is often dyspneic, cyanotic, extremely restless, or comatose. If conscious, he is apprehensive. He vomits frequently and his extremities are cold. There is precordial pain. The heart is usually greatly dilated and the sounds are extremely weak. Gallop rhythm or more complex irregularities may be present. The pulse is usually rapid, irregular, and of low tension. The urine is scanty and highly colored. Fever may or may not be present. Often the temperature is subnormal. The liver is sometimes engorged. Such cases are often rapidly fatal. Pathologically, the myocardium alone is affected, as a rule.

Speaking of the occurrence of endocarditis during the course of acute specific infections, Chapin[1] goes on to say that the appearance of a murmur is often the first definite evidence of the development of valvular disease. In most of such cases the condition is not recognized until late in the convalescent stage. Early pericarditis is usually only discovered by auscultation during the course of routine examination. With extensive effusion there is an increase in the outline of the cardiac dullness. The outline is pear-shaped with the base downward. In combination with such an increased area of dullness, the absence of the apical impulse is significant. Because of the extreme distention of which the pericardial sac is capable, the embarrassment of the heart action is not often marked. Rise in temperature, otherwise unexplainable, should attract attention to the possibility of the existence of valvular involvement or pericarditis.

Newburgh,[3] in discussing cardiovascular disturbances in acute infections, says that the vaso-

motor apparatus suffers no damage and that the functional activity of the myocardium is, as a rule, not seriously impaired. He argues logically against the use of strychnin and caffeine as cardiovascular stimulants.

The Heart in Diphtheria

Cardiac complications were the cause of 15 per cent of the deaths in a large epidemic of diphtheria according to Hitchcock [4]

Of all specific infections, diphtheria exercises the most especial effect upon the heart. Cardiac involvement in this disease is so frequent and of such vital significance as to occasion a considerable amount of investigation of its cause and manifestations. The electrocardiograph has proved of inestimable value in the early detection and diagnosis of such involvement.

The Myocardium

The myocardium is the most frequent site of cardiac pathology in diphtheria. Hume[5] describes the clinical picture presented in such cases.

In confirming the diagnosis of myocarditis, Hecht[6] uses the x-ray. He is able to demonstrate dilatation in the roentgenogram in 25 per cent of the cases. The electrocardiograph, also, is coming into general use as a means of detecting the existence of myocardial involvement.

Hecht[6] says that an accurate estimate of the integrity of the heart muscle can be drawn from the comparison of wave excursions of the electrocardiogram. He shows tracings from severe and from fatal cases which he interprets, from the diminution in the excursions or the complete absence of the P, R, and T waves, as indicative of severe heart damage. Frequently in such cases the excursion of the S wave is increased, returning to normal as the patient improves. In one patient with clinical manifestations of cardiac syncope, and with extrasystoles of left ventricular origin, the R waves in leads I and II were so low as to render distinction from the P wave difficult. As a similar case recovered the R wave increased in amplitude, a negative P wave assumed its normal upright position, and a delay in conduction became shorter. In another case in which nodal rhythm was present, the impulse apparently arising in the junctional tissue to the ventricular side of the A-V node, the P wave was iso-electric, the T wave diphasic, and the R wave low and broad. Later, the R wave was definitely split. As recovery progressed, the P wave became positive and both the P and the R waves resumed more nearly normal distances of excursion. Hecht assumes that such wave form changes are significant of pathology of the myocardium.

Rohmer[7] observed similar changes in the forms of the waves of the electrocardiogram and construed them as evidence of gross myocardial insufficiency.

In patients dying from cardiac failure, Hecht[6] usually finds more or less diffuse fatty degeneration of the auricular and ventricular muscle fibers, and diffuse round cell infiltration of the interstitial tissue.

In the cases examined by Hume[5] the ventricles seemed to be the especial sufferers in the pathological process. They were usually grossly damaged, while the auricles suffered to a minor extent. Fatty degeneration of the muscle fibers and round cell infiltration of the interstitial tissue were the most marked pathological processes.

Similar localization of the most extensive pathology in the ventricles is described by Price and Kennedy.[8] Degeneration of the auricular myocardium was slight. There was no evidence of damage to the nerve trunks or the ganglionic masses in the posterior auricular walls.

Tanaka[9] concludes that lesions of the conduction system are certainly most rarely the cause of cardiac death. Rather it is dependent mainly upon damage to the myocardium, with or without accompanying conduction tissue destruction. Of 15 cases dying in cardiac syncope studied by him, fatty myocardial degeneration was present to a greater or less degree in 14. Interstitial infiltration with polynuclear and mononuclear leukocytes and eosinophiles was observed in 6 of those cases. Fragmentation of the muscle fibers was observed only once. It is also reported by Fleming and Kennedy.[10]

Heilhecker[11] reports similar findings in 4 of 6 cases examined by him. The 2 cases in which there was no myocardial pathology had not exhibited clinical manifestations of myocarditis, and are described as dying of toxemia. He emphasizes the occurrence of hyaline degeneration of the muscle fibers in addition to the fatty degeneration usually described.

The interstitial changes were striking in the cases reported by Aviragnet, Lutembacher, and Le Soudier[12]. The parenchymatous lesions were no less noteworthy but were not of the fatty and fibrous nature so often described. They occurred principally in the left ventricle and were most severe near the primary focus of the interstitial lesions. The fibers were swollen, vacuolated, often fragmented, and in the center of the lesions there was only a liquefied mass with débris of cardiac fibers and some mononuclear cells. Striations had disappeared, and the nuclei were pale and misshapen. Inflammatory nodules consisting of masses of mononuclear cells and fibroblasts were seen on the left side of the interventricular septum.

Nuzum,[13] in examining the heart in 29 cases of diphtheria, found an eosinophilous myocarditis in 7. Such a condition was not present in many cases of death from various other acute infectious diseases. It is also mentioned by Tanaka.[9] The degree of eosinophilic infiltration exhibited no relation to the severity of the clinical symptoms or to the extent of the myocarditis.

D'Espine and Mallet[14] reported the presence of parietal thrombi in both auricular and ventricular walls as well as a parenchymatous myocarditis in a case of diphtheria dying in cardiac syncope.

Irregularities and Functional Disturbances

Hume,[5] in discussing cardiac irregularities in diphtheria, finds that premature auricular contractions occurred in 5 of 18 cases which he collected. They were the only type of irregularity noted in mild and moderately severe cases with the exception of sinus arythmia. They were unaccompanied by major symptoms of cardiac embarrassment and usually persisted for only a few days. In 4 cases described by him, premature beats, certainly of auricular origin in 2 cases and probably so in the other 2, were the precursors of, or accompanied by, other and graver irregularities. They were frequently observed in combination with other severe disturbances of rhythm. Gunson[15] reports auricular extrasystoles as occurring in 28 per cent of 120 cases of diphtheria. He considers them as frequently of no significance, as they are often unattended by subjective symptoms. In 5 severe cases they occurred very frequently and were accompanied by decompensation and gallop rhythm.

Premature ventricular contractions were noted as the only irregularity in one of Hume's 18 cases. In another case they were accompanied by auricular extrasystoles.[5] Gunson[15] failed to note them at all in his study of 120 cases.

Auriculoventricular extrasystoles were noted by Gunson.[15]

Among Hume's[5] 18 cases 2:1 heart block was noted in 3, and complete heart block in 7. In one of his fatal cases 2:1 heart block was present and block of an undetermined rhythm was probably present in another. Hecht[6] reports 2 cases of heart block; in one of them the rhythm was 2:1 and neither the auricular nor the ventricular rate was markedly or constantly accelerated by the administration of atropin, even when given in sufficient amount to produce poisoning.

Block of all degrees from isolated blocked beats to complete dissociation of the auricles and ventricles is certainly by no means rare.

Hume[5] noted nodal rhythm in 7 of his 18 cases. Such independent contraction of the auricles and ventricles in response to simultaneous-stimulation from a common source in the A-V junctional tissue was certainly noted in 2 of his fatal cases, and probably in another. Hecht[5] and Belskii[16] described cases of nodal rhythm. In several of the cases described the region of the S-A node and the node itself have been involved in severe degenerative processes while the region of the A-V node has been unaffected. Hence a pathological basis for the shifting of the impulse origin-site has been established.[17]

Wilson[17] quotes Lewis, and Meek, and Eyster in explaining the mechanism of nodal rhythm. The development of such a rhythm is the result of a displacement of the pace-making function from the S-A node to a point lower down in the conduction system. Such displacement has been demonstrated by these men in dogs following a slowing of the heart by vagus stimulation.

Hume[5] noted the occurrence of auricular flutter in two fatal cases. The auricles were contracting at a rate of nearly 500 beats per minute. He assumes these auricles to have been in flutter because there is no record of over 350 beats per minute in cases of flutter in adults.

Tachycardia is as frequently encountered in diphtheria as in scarlet fever according to Hecht.[6] He shows electrocardiographic tracings of cases with very high pulse rate, short or absent diastolic pauses, and superposition of the P and T waves. Hume[5] met with paroxysmal tachycardia in a fatal case of diphtheria. He is uncertain as to whether the generating focus was in the auricular muscle or the A-V junctional tissue.

Two cases of sinus bradycardia with pulse rates of 44 and 60 respectively were observed by Hecht.[6]

Sinus arythmia was observed by Hecht.[6] He considers it of no significance in diphtheria. It was noted as being of an exaggerated nature in two cases of severe nephrosis complicating diphtheria.

Hecht[6] concludes that, as a rule, the conduction time is not markedly affected in diphtheria. The average P-R interval in 46 cases was 0.130 seconds to 0.140 seconds. In one case of 2:1 heart block described by him the conduction time was 0.180 seconds to 0.220 seconds and was increased to 0.240 seconds by the use of digitalis. Four months later the tracings in this case were essentially normal.

Conduction Tissue Pathology

There has been much discussion as to the frequency of the occurrence of clinically demonstrable disturbances of conduction without demonstrable lesions of the conduction system. Certainly there is often no parallelism between the anatomical lesions and such conduction changes as are manifested clinically. Anatomical lesions of the His bundle alone are rare, although it is not uncommon to note disturbances of conduction without clinical evidence of myocardial damage. Often lesions of the myocardium cause no clinical symptoms, but invariably the slightest lesion of the bundle produces marked clinical manifestations of conduction changes.[12]

Hume[5] reports two cases of gross irregularity in one of which premature auricular beats, nodal rhythm, and auricular flutter were demonstrated; but the nearest approach to a lesion of the A-V node or bundle found at autopsy was a slight increase in vascularity. The postmortem findings were similar in the other case, in which he was unable to determine whether the irregularity was nodal rhythm or heart block associated with auricular fibrillation. Rohmer[7] observed two cases of complete auriculoventricular dissociation. Pathological examination in these two cases revealed scarcely any damage to the bundle itself —certainly not enough to account for the clinical findings, although there was extensive fatty degeneration of the muscle fibers and round cell infiltration of the interstitial areas of the interventricular septum. He concludes that the diphtheria toxin exerts an influence on the functional activity of the bundle, but that it rarely so damages it as to produce demonstrable histological changes. It is assumed from such descriptions that lesions of the conduction tissue are certainly not always present in cases of clinically demonstrable irregularity.

On the other hand, the extensive parenchymatous degeneration in the case of complete heart block described by Magnus-Alsleben[18] involved the A-V bundle. Fleming and Kennedy[10] report a case of heart block in diphtheria in which the A-V node and the proximal part of the bundle were involved in an inflammatory process consisting of intense round cell infiltration and marked capillary engorgement. They, with Magnus-Alsleben, hold that there is a close connection between disease of the bundle and disturbances of conduction. Hume[5] reports a case of heart block with nodal rhythm in which there was an advanced acute inflammatory process throughout the region of the S-A node and a definite capillary engorgement in the A-V node and bundle. Price and MacKenzie[8] report postmortem findings in a case of block and auricular fibrillation. The S-A node and the tissue about it were normal as were the A-V node and bundle. However, the interventricular septum in the immediate neighborhood of the A-V node was the seat of an extensive inflammatory infiltration. It is possible that the conductivity of the specialized tissue was disturbed by the gross neighborhood destruction. Aviragnet, Lutembacher, and Le Soudier[12] describe a case in which marked irregularity—extrasystoles, partial block, and, finally, complete block—occurred transiently. For a few days before death the rhythm was normal. Upon postmortem examination the bundle was found to be the seat of extensive interstitial and myocardial degeneration. Reviewing a number of cases reported in the literature, they state that a physiological basis for conduction changes must often be assumed as frequently no anatomical lesion is present to explain them. These authors sum up the situation as it stands at present very well.

Tanaka[9] reports 3 cases of marked irregularity, 2 of them definitely stated as being heart block. In these cases there was extensive degeneration of the A-V bundle. He thinks that the irregularities were certainly due to lesions of the conduction system. In 14 of 15 fatal cases examined by him there was more or less extensive degeneration of the conduction tissue.

In the 3 cases mentioned above there was little or no mycocardial pathology. He takes the stand that death as a result of conduction tissue pathology alone is rare. Heilhecker[11] demonstrated fatty degeneration in the A-V bundle in 2 of 4 cases dying in cardiac syncope. No mention is made of the existence of any irregularity, however. He quotes the case described by Magnus-Alsleben, and concludes that dissociation or lesser

18. Magnus-Alsleben, E.: Zur Kenntnis der Vorubergehenden über leit ungs-storungen des Herzens, Ztschr. f. klin. Med., Berl., 1910, lxix, 82.

grades of conduction change are liable to occur when the conduction tissue becomes involved in an inflammatory process; but he questions the assertions of Moneckenberg and Amenomiya to the effect that death might often be attributed to isolated involvement of the conduction tissue without coexistent myocarditis. In a very recent article Nuzum[13] concludes that there is a possibility that the various types of arythmia in diphtheria are due to a compression of fibers in the bundle of His as a result of moderate cloudy swelling or to degenerative changes in this system. Such changes in the conduction tissue are never proportional to the degenerative changes present in the myocardium.

The Endocardium and the Pericardium in Scarlet Fever

Chapin[1] says that endocarditis and pericarditis are especial complications of scarlet fever. They usually develop during the second or third weeks of illness, and a rising pulse rate is the commonest early sign. Nobécourt and Milhit,[19] discussing cardiovascular disturbances during the course of scarlet fever, say that endocarditis occurred in 0.58 per cent of the cases. It may occur early or late in the course of the infection. It is often very late. Although rarely fatal, it seldom clears up completely. Most frequently, though not as often as has been supposed, it assumes a chronic course, *i.e.*, the murmur, and perhaps vague symptoms referable to the organic lesion, persist. Mitral regurgitation is the most frequent lesion. Pericarditis occurs alone or in association with endocarditis. As a rule, it is latent and subsides rapidly. It is described as dry, serofibrinous, or purulent. The purulent cases are always fatal. Both conditions are ascribed to secondary infection.

The onset of acute endocarditis has been reported as occurring during practically all of the acute infections but, according to Nobécourt,[20] 4 to 5 per cent of the cases occurring before the third year are due to scarlet fever. Of course, it is very rare during the first two years of life and a vast majority of the cases are rheumatic in origin. Murmurs in such cases as do develop at this age are described as difficult to distinguish from functional murmurs. They are usually soft, tending to disappear and recur. There is usually slight dilatation, but rarely pain, palpitation, or dyspnea. Fever may or may not be present.

21. Nobécourt, P.: Rheumatisme Articulaire Endocardite et Pericardite dans la Scarlatine, Jurie des Camiers & Tournier, Bull. et mém. Soc. de méd., de hôp. de Paris, 1915, 3. s., xxxix, 793.

In another article the same author, with his associates des Camiers and Tournier,[21] discusses the frequency of the occurrence of endocarditis and pericarditis in scarlet fever. Of 262 cases studied by them, 22 developed rheumatism and of these 22, six developed endocarditis which was associated in two cases with pericarditis. The mitral valves were affected in all 6 cases, and in 2 the aortic valves were involved as well. All 6 cases recovered.

Gunson[22] reports a case of scarlet fever seen on the thirtieth day of illness in which there was no previous history of rheumatism, or of symptoms referable to organic heart disease. At the time of admission there was present a mitral regurgitant murmur. A few days later a pulse irregularity due to premature contractions was detected, this irregularity lasting two days. Ten days after admission pericardial friction rubs were heard, and various joints became involved in an acute inflammatory process. The patient died and autopsy revealed the existence of a recent fibrinous pericardial exudate. The parietal and visceral pericardial layers were completely but loosely adherent. There were numerous small subepicardial hemorrhages. The mitral and tricuspid valves were thickened, and there were vegetations on the mitral valves as well as on the wall of the left auricle. Goffe[23] reports a case of pericarditis developing in the course of scarlet fever in a patient which had a previous history of rheumatism, but none of cardiac trouble. The patient developed symptoms of myocardial insufficiency and died in cardiac syncope. A double murmur was present, presystolic and systolic at the apex, with a pericardial friction rub. At postmortem examination vegetations were found on the mitral and aortic valves; both pericardial layers were covered with recent exudate.

Cantley[24] reports a case of pulmonary regurgitation developing during the course of an attack of scarlet fever. The right side of the heart was enlarged and there was a long, low, diastolic murmur heard best over the pulmonary valve area. It varied in intensity in all directions. The patient recovered.

Myocardial Changes in Scarlet Fever

Nobécourt[25] emphasizes the occasional occurrence of myocardial dilatation during the course of scarlet fever. In such an event such symptoms

24. Cantley, E.: Case of Pulmonary Regurgitation Before Roy. Soc. of Med., March 26, 1915, Rev. Brit. Jour. Child. Dis., 1915, xii, 143.
25. Nobécourt, P.: Les Dilatations et Hypertrophies du Couer, les Troubles du Rhythme Cardiaque Chez les Enfants, Jour. de méd. de Paris, 1913, 2s, xxv, 915.

of myocardial weakness as dyspnea, cyanosis, extreme restlessness, and scanty albuminous urine are evident[19]. Cases of sudden death in typical cardiac syncope in scarlet fever have been reported.[22 23] Nobécourt and Milhit[19] also say that symptoms referable to the heart occur in cases of severe scarlatinal nephritis. The clinical picture of myocardial insufficiency is presented by sudden dilatation of the heart and sudden enlargement of the liver. Gallop rhythm was noted at some time or other in practically every case of nephritis. In such cases it is evident that a latent myocarditis had long been present.

Hecht[6] advises the exercise of considerable reserve in the interpretation of form changes of the electrocardiogram, but he thinks that such changes are very probably indicative of myocardial pathology. He studied 59 cases of scarlet fever with the electrocardiograph. During the height of the illness, in 9 cases, the excursions of the S wave in one or more leads was often markedly increased resuming more nearly normal excursions as recovery progressed in some of them. To such sudden increase of the S wave he attaches grave portent, although it is often significant only of the normal relative preponderance of one ventricle over the other. Splitting of the R or S waves was definite in 4 cases and indefinite in 3. Only one case in which a split R wave was observed was severe; hence he assumes that such splitting may be accidental although it is rarely observed in normal electrocardiograms. The P wave was split in one or more leads in 7 cases, only once in all 3 leads. As he had never noted this occurrence in normal tracings, he assumes that it is an indication of over-exertion of the auricles. As it occurred only in severe or fatal cases, it must be considered as of grave import. Very low excursions of the R wave were noted twice. In one case this wave resumed a normal height as the patient improved. In 2 rapidly fatal cases the T wave was unusually high. He concludes that such increased excursion is not necessarily an indication of good quality of the muscle although possibly a toxic central or peripheral accelerator stimulation might account for both the tachycardia and the high T wave. No evidence of severe disturbance of conduction was noted. In one case the length of the P-R interval was 0.180 seconds to 0.200 seconds, in two cases 0.180 seconds, in ten 0.160 seconds, and in one 0.156 seconds. Hecht considers these as delays since his own figures of the P-R interval in twenty-five normal cases averaged 0.140 seconds. In most of these cases the conduction time became shorter as the patient improved. He cites a case in which a P-R interval of 0.190 seconds at the height of the illness dropped to 0.160 seconds fourteen days later.

Usually 0.170 seconds is considered as the upper limit of the normal P-R interval.[17]

In a study of cardiac pathology in scarlet fever, Stegemann[26] found that myocardial fatty degeneration, interstitial round cell infiltration, and areas of necrosis occurred frequently in the long drawn out cases but are seldom seen in the rapidly fatal ones. He concludes that the toxin of scarlet fever probably exerts no pathological influence upon the conduction system.

Irregularities and Functional Disturbances

Nobécourt and Milhit[19] do not think that functional derangements of the heart in scarlet fever are the result of definite myocardial pathology. Rarely are myocardial lesions found to be present upon postmortem examination of cases in which such functional manifestations have been exhibited.

Monier-Vinard and Meaux-Saint-Marc,[27] studying the cardiac rhythm in 270 cases of scarlet fever, considered tachycardia to be the rule during the febrile period. They attached an unfavorable import to the existence of severe tachycardia. Hecht[6] observed a primary tachycardia in 9 of 59 cases. Electrocardiographically these cases usually showed a normal conduction time, but practically no diastolic pause. In 2 of the cases in which the pulse rates were 186 to 200, superposition of the P and T waves was noted. Nobécourt and Milhit[19] say that tachycardia is usually present from the onset even in the mildest cases and persists until the afebrile stage. In severe cases the heart often assumes a rate of 180 to 200 beats per minute. Nobécourt[25] also speaks of the frequency with which tachycardia persists far into the convalescent stage. Tachycardia is usually associated with low blood pressure.

Bradycardia attracts considerable attention in recent discussions since its occurrence has only lately been noted. In their study Monier-Vinard and Meaux-Saint-Marc affirm that bradycardia occurred at some time during the course of the infection in 32 per cent of the cases. It usually occurred after the fall of the temperature or during the fading of the rash. It was much more frequent in adults, occurring in 76 per cent of the cases. The average pulse rate in the cases in children was 64, in adults 50. They considered bradycardia to be an indication of an exaggerated

inhibitory vagus action. It was transient, irregular, and easily affected by numerous influences, such as slight temperature rises, or by mild exercise. It was considered as of negligible significance. It was noted late in the second week of illness by Hecht[6] in only 2 of his 59 cases. One patient had a severe nephritis. In neither case was the pulse high during the febrile period. He attributes its causation to increased vagus inhibition. Nobécourt and Milhit[19] observed bradycardia only occasionally.

Sinus arythmia was observed in 10 of Hecht's 59 cases.[6] In 5 of these cases there was no clinical evidence of organic heart disease; in 2, however, there were minor evidences of myocardial insufficiency and in 3, organic valvular defects. The arythmia was of an especially exaggerated character in two cases of marked bradycardia. Nobécourt and Milhit[19] made a similar observation. They say that sinus arythmia is the most frequent disturbance of rhythm in scarlet fever and that it is rarely observed during the febrile stage.

Extrasystoles are mentioned as occurring during the course of scarlet fever by Nobécourt and Milhit,[19] Nobécourt,[25] and by Gunson.[22] They are more frequent in adults than in children, and have been observed only in cases of myocarditis or nephritis associated with hypertension.

Belskii[16] has demonstrated the existence of nodal rhythm in cases of severe scarlatinal myocarditis.

Pneumonia

Organic Lesions. Involvement of the endocardium, myocardium, and pericardium are not infrequently observed in pneumonia.[1] Nobécourt[28] says that pericarditis is as frequently a complication of pneumonia as of local pyogenic infections in children under five years of ago. Tivey[29] reports a case in an infant of nineteen months. Nobécourt[25] remarks upon the occasional occurrence of the myocardial syndrome and Chapin[1] dilates upon the same condition. He attributed the critical collapse so often observed in pneumonia as due either to myocardial weakness or vasomotor paresis. The obstruction to pulmonary circulation is given as one of the chief causes for the strain upon the heart.

Nobécourt[25] mentions the frequent occurrence of the various physiological arhythmias in convalescence from pneumonia.

Zahorsky[30] reports a case of paroxysmal tachycardia following bronchopneumonia. For 8 months following the initial illness there were recurrent attacks in which the pulse rate rose to 200 or over per minute. During such attacks the patient was badly prostrated. Parkinson[31] describes a case of heart block occurring in pneumonia. Magnus-Alsleben[18] presents polygraphic tracings showing partial dissociation occurring during the course of convalescence from pneumonia in a patient who had received digitalis medication. He mentioned a similar phenomenon as having occurred during three other cases of pneumonia, the irregularity being transient in each case. Hence he assumes that there was no gross pathological damage to the conduction system.

Digitalis Medication

Cohn[32] gives digitalis to pneumonia patients routinely as an effort toward preventing auricular fibrillation. He gives digipuratum in doses of 0.4 gm. daily. The total amount given is never more than 2.0 gm.

In investigating the action of digitalis upon the heart in pneumonia, Cohn and Jamieson[33] studied 105 cases with the electrocardiograph. Digitalis was administered to 49 cases, while 56 were studied as controls. The increased length of the P-R interval and changes in the form of the T wave were taken as criteria of the effect of the drug.

Changes in the conduction time, or in the form of the T wave were noted after practically the same lapse of time and the administration of similar amounts of digitalis as had been previously observed in afebrile cases. Of 36 cases of pneumonia receiving sufficiently large doses (0.8 gm. of digipuratum by mouth) to produce an effect on normal cases, 97 per cent showed an effect. Changes were noted both in the P-R intervals and the T wave in 77.7 per cent; in the T wave alone in 16.6 per cent; and in the P-R interval alone in 2.7 per cent. Changes developed more quickly and oftener in the T wave than in the P-R interval. Cohn thinks that it is unlikely that the toxin elaborated in pneumonia has any special influence on the T wave. Because of this he considers his results as purely digitalis effects.

Of the 50 controls receiving no digitalis, no changes were noted in the electrocardiograms of 88 per cent; there were changes in both the P-R interval and the T wave in 4 per cent, and in the T wave alone in 8 per cent.

In 5 cases in which the auricles were fibrillating, the high ventricular rate was reduced

during the febrile period by the use of digitalis.

As regards cardiac pathology in pneumonia the work of Liebmann is quoted by Cohn.[33] In 3 of 11 cases Liebmann found inflammatory infiltrations so located that they might readily have produced disturbances of rhythm. Eyselein is also quoted. In only 4 of 23 cases examined by him was there evidence of myocardial damage. This consisted of fatty degeneration, mild in one case and advanced in 3.

Heart Studies in Influenza

Lebreton[34] presents the fullest early account of influenza endocarditis. He analyzed 21 cases of endocarditis in which the influenza bacillus was obtained either from sputum or blood culture; but in only 3 of these were the organisms recovered in pure culture from the affected heart valves. In 9 more cases other organisms as well as the B. influenzae were recovered. In Lebreton's judgment these 9 cases might truly be classified as of influenzal etiology.

Endocarditis may occur during the early febrile period or may develop during convalescence. It is much less frequent in children than in adults. Phenomena leading to its diagnosis in influenza are palpitation, precordial pain and tenderness, chills, or fever unexplainable otherwise. Its development may be anticipated with some accuracy if a blood pressure which is already low falls still lower. The development of a murmur or a change in the character of a murmur already present, should such a situation exist, in the presence of the above mentioned features clinches the diagnosis. It is rarely malignant. Frequently in such cases there are terminal pulmonary infarcts, or renal, hepatic, splenic, or arterial emboli.[34]

Simons,[35] in an analysis of 325 cases of acute and chronic endocarditis, considers influenza endocarditis as rare, and never the cause of the chronic infectious, endocarditic processes. He seems to think that in those cases of chronic endocarditis considered as of influenzal etiology the probability is that the influenza infection is engrafted upon a previously existing rheumatic process. Of 96 cases of chronic endocarditis analyzed by Simons the influenza bacillus was considered by Libman as the infective agent in only 4. It is assumed that 11 cases, 6 of which were diagnosed clinically and 5 at postmortem examination as influenza endocarditis, were acute.

Malloch and Rhea[36] report 2 cases of endocarditis developing during the course of acute illnesses. Both patients died of bronchopneumonia. The influenza bacillus was recovered in smear or culture from the terminal bronchioles, the heart blood, and the aortic cusps of the one case; and from the terminal bronchioles and the aortic and mitral vegetations of the other. In the first case, there were fresh vegetations on the aortic cusps and evidences of a recent toxic myocarditis. In the latter case, vegetations were found on both aortic and mitral valves. There was also an excess of clear fluid in the pericardial sac and minute subepicardial hemorrhages. They conclude that of 47 cases reported in the literature, including their own, only 16 were certainly of influenzal etiology.

Eichhorst[37] affirms that mechanical damage of the heart is rare in influenza. He observed 2,411 cases of influenza with 351, 14.6 per cent, deaths. In only 2 cases were there fresh valvular vegetations. These were situated on the mitral valve and their presence had not been suspected during life. They were so insignificant as to have certainly not disturbed cardiac function. In 2 cases a serofibrinous pericarditis occurred. No gross pathology of the heart muscle was noted nor in the many hearts examined miscroscopically was there any evidence of fatty degeneration or interstitial infiltration. In 4 non-fatal cases mitral insufficiency developed. These cases had no evidence of previously existing valvular defects. This complication occurred at the end of the first week in 3 cases and at the end of the second week in the other, at that time afebrile. All the cases were discharged without evidence of existing valvular defect, although one patient returned 2 weeks later complaining of precordial pain.

Irregularities and Functional Disturbances

In contradistinction to the rarity of organic lesions, Eichhorst[37] observed functional derangements so very frequently as to conclude that they were essentially specific peculiarities of influenza.

Tachycardia was observed in four cases, in both the febrile and the convalescent period. It was quite transient. Eichhorst[37] goes so far as to say that tachycardia was the initial symptom of influenza in one case. Smith[38] studied ninety-five cases of tachycardia observed in convalescence from influenza pneumonia. There was no organic cardiac basis for the tachycardia in any of these cases. In 37.8 per cent of the cases there was a previous history of cardiac irritability and of a possible etiologic factor for this irritability in a great majority of these cases; 40 per cent, however, had no previously established physical basis

for the tachycardia, although many of this group normally had rapid pulses. In 20 per cent hyperthyroidism was suspected.

The atropin and epinephrin tests were given in fifty cases. The results in nineteen suggested a hypotonic vagus nerve, and in twelve a hypersensitive sympathetic nervous system.

Bradycardia was encountered very frequently both in the febrile and the convalescent periods by Eichhorst.[37] It was most frequently observed in cases with severe bronchopneumonia. In contrast to tachycardia, it was quite persistent. It was present in some cases for as long as six months after the initial illness. There were very minor subjective symptoms connected with it.

Extrasystoles were observed frequently. They were transient or persistent, and their subjective symptoms were of negligible importance.

Cardioneuroses were observed in three patients in whom the infection ran a prolonged febrile course.

Cockayne,[39] like Eichhorst, finds bradycardia a very frequent occurrence in influenza. Altogether 168 cases were observed, in 132 of which the pulse rate fell below fifty per minute; fifty-five cases were studied with the polygraph and it was found that in nineteen of these the bradycardia was due to partial heart block. Sinus block was present in one case; prolongation of the a-c interval in two; 2:1 block in nine; and 3:1 block in six. It is probable that more such cases would have been demonstrated had all the cases been studied polygraphically. All these patients had pneumonia. He concludes that it is probable that bradycardia and heart block are frequently the effects of the toxin of the influenza bacillus. Atropin in sufficient doses to produce poisoning had no appreciable effect in the cases of block, and but very little in the simple bradycardias. The effect of amyl nitrite in the latter group was very transient. Hecht[6] noted 2:1 block in one case of influenza and complete dissociation in another.

Hecht[6] says that sinus arhythmia occurs frequently in measles, usually appearing in an exaggerated form in the postfebrile stage. According to Hecht, sensitiveness of the vagus nerve is one of the outstanding features of measles. He shows electrocardiographic tracings of three cases in which the postfebrile sinus arhythmia was very marked. He also had a case in which 2:1 rhythm developed, and another in which there was complete dissociation of the auricles and ventricles. Influenza was possibly a complication in both these patients, however, and Hecht attributes the conduction disturbance to influenza rather than to measles. At any rate, he could find no report of conduction derangement in measles.

There have been no investigations of any note concerning the behavior of the heart in meningococcus meningitis, and very few case reports. Hecht[6] made electrographic tracings from cases of meningitis in which the heart rate was irregular. He concluded that all such arhythmias were simply manifestations of vagus pressure. They were not usually relieved by lumbar puncture, but frequently the increased inhibitory function of the vagus was counteracted by the use of atropin. As might be expected in vagus stimulation, the pulse was usually slow.

Of 265 cases of epidemic meningitis treated by Herrick[40] at Camp Jackson, pericarditis was a complication in eleven and endocarditis in one. There were only three cases of pericarditis and none of endocarditis among those patients who received intensive intravenous and intraspinal therapy. Mackarell[41] reports postmortem findings in two cases of meningococcus endocarditis, the lesions occurring on the mitral valve in both cases.

Nobécourt[25] mentions the frequent occurrence of bradycardia in meningitis and ascribes it to abnormal excitation of the vagus nucleus or trunk.

Typhoid Fever and Heart Lesions

Nobécourt[25] and Chapin[1] mention the occurrence of myocarditis and endocarditis in typhoid fever and also the development of the physiological arhythmias during the febrile course or in convalescence. With tachycardia the blood pressure is often low. Bradycardia is attributed to stimulation of the vagus center by the typhoid toxin.

Magnus-Alsleben[18] describes the occurrence of 2:1 heart block with lengthening of the a-c interval in a case of typhoid fever. There were no subjective symptoms and the irregularity persisted for only a few days. From this fact he argues against the existence of a gross anatomical lesion of the conduction system.

Tuberculosis

Delorme[42] says that next to rheumatism, tuberculosis is the most frequent cause of pericarditis with adhesions. He discusses the physical signs of cardiopericardial adhesions in such cases. Hypertrophy and dilatation are frequent, of course.

42. Delorme, E.: Des signes et die dingnostic de la symphyne cardio-pericardique, Gaz. de hôp, 1914, lxxxvii, 147.

Fixation of the apex, once considered practically pathognomonic, is a helpful diagnostic feature when accompanied by other definite signs. The disappearance of the apex impulse, pericardial undulation as demonstrated by the x-ray, systolic retraction of the apex, epigastrium, and of the posterior intercostal spaces, invariability of the outline of cardiac dullness, diminution of the diaphragmatic movements, inspiratory recession of the lower sternum and chest, are all valuable signs.

Nobécourt[43] states that tuberculosis, next to rheumatism, is the most frequent cause of pericarditis in children more than seven years of age. He says also[43] that the mediastinum is nearly always involved in pericardial adhesions. In tuberculous pericarditis, the heart is rarely large and may be atrophied. It is often associated with tuberculous peritonitis.

INFLUENZA AND PREGNANCY—COLLECTIVE ABSTRACT

By S. A. WEINTRAUB, M.D., St. Louis

IN view of the possibility of a return of last year's pandemic of influenza, it becomes desirable to study literature for an answer to two questions: (1) Does pregnancy act as a predisposing factor in the contraction of influenza? and (2) Does influenza take a more serious course with a higher mortality when complicated by pregnancy?

Influenza is chiefly a disease of adult life, and attacks individuals in their physical prime. In approximately 50 per cent of the cases the patients are found between the ages of twenty to thirty years.[1] We know that pregnancy occurs more frequently during the first ten years of marriage, that is, at approximately the same age period, between twenty and thirty. It follows, then, that influenza is most likely to attack women during the period of their highest productivity; so that while statistics would apparently show the pregnant woman more susceptible to influenza, this fact might be solely due to this coincidence. It is the view of Kosmak[2] and Farrar[3] that pregnancy does not increase the susceptibility to influenza.

Influence on Mortality Rate

Does influenza present a higher mortality when complicated by pregnancy? In discussing this question several facts must be taken into consideration. We must differentiate between the uncomplicated mild form of influenza and the severe form with complications, and must also consider in which period of pregnancy the disease is contracted.

In the so-called mild form of influenza, we find the usual infection of the upper respiratory tract with the general systemic complaints, but without pneumonic symptoms. In these cases the patient, as a rule, recovers occasionally after having aborted.[4]

The frequency with which pregnancy is interrupted seems to depend upon the severity of the infection, toxemic or septicemic type, the general physical condition of the patient, and the stage of pregnancy. Even without complications, influenza shows various degrees of virulence, variations in temperature, in the general systemic symptoms and in cough. The symptoms vary with the individual. A more pronounced toxic or septic process would, of course, exhibit a greater tendency to interfere with the further progress of pregnancy. A state of good health is undoubtedly a factor in combating the septic type of the disease and so offers protection against its untoward effect on pregnancy. Healthy pregnant women react as well as the non-pregnant.[2]

The earlier the stage of pregnancy the greater the frequency of abortion from influenza.[3] This is probably due to the fact that the ovum in its earlier stages is not yet firmly imbedded. The high percentage of spontaneous abortion in early pregnancy must also be taken into consideration.[5]

Bland[6] found that about 40 per cent of pregnant women attacked by influenza aborted or miscarried, while Harris, in a series of 626 uncomplicated cases collected from literature, figured the frequency of interruption as 26.3 per cent. The percentage would be higher, of course, if only the early pregnancies were considered.

Influenza, however, produces a distinct lowering of resistance towards bacterial invasion, and this is the accepted cause of its frequent compli-

cation with pneumonia.[7] This fact obviously applies to the pregnant woman as well as to the non-pregnant. The percentage of influenza patients developing pneumonia varies from 5 to 10 per cent solely among male patients,[8] to 16.4 per cent considering both males and females.[9] The incidence of pneumonia in influenza, however, is markedly greater in pregnant than in non-pregnant women. Calderon[9] states that 78.4 per cent of his pregnant influenza patients developed pneumonia, while Harris reports only 50 per cent. In their opinion, an apparent lack of resistance of the gravida against pulmonic complications is responsible for the high mortality of all types of pneumonias among pregnant patients. This tendency of pregnancy towards pulmonic involvement is particularly evident in cases of influenza. A further analysis of the figures of Bland and Harris, given above, shows a marked increase in the percentage of interrupted pregnancies among patients suffering from an influenzal pneumonia. According to available figures in complicated cases, the interruption of pregnancy seemingly occurs as frequently in the early months of gestation as in the latter months;[10] but if the unknown number of spontaneous abortions could be subtracted, we might find that later abortions and premature labors probably are more frequent than the early interruptions. This relation does not seem to prevail in the simple influenza cases without complications.

A Serious Aspect

The interruption of pregnancy presents a serious aspect.[6] In 743 cases mentioned by Harris in which pregnancy continued undisturbed, there was a maternal mortality of only 16 per cent; while in 468 cases in which pregnancy terminated prematurely the mortality amounted to 41 per cent. He draws from this fact the conclusion that interruption of pregnancy renders the prognosis more grave. This is evidently true, but the fact must be considered that the termination of gestation often is but a secondary manifestation of the severity of the infection and that if the toxemia, or more probably the septicemia, is of severer nature, pregnancy is more apt to be disturbed. Not the expulsion of the contents of the uterus in itself, but the greater violence of the infection in cases of interruption, makes the outlook for the patient less hopeful. This is particularly true if the termination occurs before or during the height of the attack. When the interruption occurs after the crisis or during the lysis, the prognosis both for the mother and the viable fetus is better. In Lupton's[11] five cases of whom four died, the one surviving patient had the crisis six days before delivery. Bland reports a maternal mortality of 69 per cent; Welz, 92.3 per cent; Woolson and Conley, 51.5 per cent; and Calderon, 65 per cent. Harris concludes that the mortality is greater in the last three months of pregnancy, figuring it as 60 per cent. This is an appalling percentage if compared with the already high mortality of 33.3 per cent for non-pregnant women.[10]

Why do influenza and influenzal pneumonia terminate pregnancy so frequently? Before attempting to answer this question we must consider the etiology of this disease.

Kinsella[12] and Ives[13] claim that influenza is a disease caused by some as yet unknown agent. On the other hand, Duval and Harris[14] report that the influenza bacillus was recovered from pneumonic lungs in 94 per cent of cases and could be recovered from sputum in every instance, although others[15] had claimed that the "nasal application of a filtrate from a pneumonic lung failed to call forth any abnormal symptoms." Blood cultures were negative, but in three fatal cases the influenza bacillus was recovered from the heart blood. They, therefore, conclude "that only occasionally, and then under conditions not understood, the Pfeiffer bacillus gives rise to a septicemia." Goodpasture[16] reports that in the early part of the epidemic the Pfeiffer bacillus was found at postmortem in 86 per cent of the lungs, often in pure culture; while, later in the epidemic, hemolytic streptococci were found in the lungs of 100 per cent of the cases at necropsy, in the majority of instances in pure culture. The British Influenza Committee[17] reports that the Pfeiffer bacillus was recovered from the blood only in two out of sixty-eight attempts. Other writers, Halliday,[18] Gatch and Wittingham,[19] Keegan,[8] Fildes, Baker, and Thompson,[20] and Little and Gorofolo[21] claim negative blood cultures. Lampe[22] believes that all manifestations of the various general symptoms are secondary to the unrecognized influenza virus. Another claim[23] that the causative virus might be found in the

blood of practically all influenza patients is based on the following experiment: A filtrate of blood from influenza patients was injected into the noses and throats of six healthy individuals, who all developed influenza symptoms. Stine[24] attributes influenza to a diplostreptococcus found both in the nasal secretions and blood stream in 80 per cent of 1,020 cases of pneumonitis studied by him.

Attribute Influenza to Filtrable Virus

Bradford, Bashford, and Wilson,[25] after a most thorough investigation, attribute influenza to a filtrable virus which was seen microscopically in the filtrate and has been cultivated therefrom. They found the organism in the sputum in every instance, and state that "during the early stages of the disease the organism is present in the blood and can be recovered therefrom as early as twenty-four hours after the onset of the illness. It persists in the blood until about two days before the declension of the fever." They claim that all the lesions of influenza have been reproduced in animals by the injection of pure cultures of an organism isolated from man, and that, therefore, all the requirements necessary to establish that organism as the cause of the disease have been fulfilled. They further believe that this organism, circulating in the blood, produces a general septicemic condition and not primarily a local respiratory disease. They also emphasize the presence of "marked lesions of a special character in the smaller blood vessels." Their communication is probably the most valuable in the maze of influenza literature. If their findings by further investigations should be confirmed, a clearer understanding of this disease and its complications can be expected and a more rational therapy with corresponding lowering of mortality might be hoped for.

Renal Complications in Influenza

The general effect of influenza on the kidneys is interesting in our special problem. Keegan reports that in about two-thirds of his cases the urine proved characteristic of severe febrile disease, but in not one case a nephritis developed. Similar observations were made by Little, Gorofolo, and Williams. Cultures of the urine were found negative by Fildes, Baker, and Thompson. Bradford, Bashford, and Wilson, however, describe an influenzal nephritis and mention two cases. In one the filtrable virus was recovered from the blood and urine; in the other from the blood during life, and from the kidneys at postmortem only.

25. Bradford, J. R., Bashford, E. F., and Wilson, J. A.: Quart. Jour. Med., 1919, xii, 259.

We must assume, therefore, that the septicemic condition, produced by this unnamed virus, leads to marked circulatory disturbances. This is most noticeable in the lower respiratory tract and the "peculiar sodden hemorrhagic lung is the result." On this injured lung is planted a secondary infection which apparently varies in different localities. While the lung is the most frequent and prominent organ affected, other tissues in the body also suffer, and it seems likely that the uterus might become involved in this manner. Hemorrhages from the non-pregnant uterus during the attack have been observed by Strouse and Bloch.[26] Practically all patients began to menstruate between the first and third day of the infection. Ameiss[27] noticed marked menstrual disturbances during the disease. Calderon also recorded the premature appearance of the menstrual flow in these cases. Engel[28] found menstrual anomalies in over 29 per cent of his cases. He mentions an interesting case in which both adnexa had been removed, followed by amenorrhoea; however, during a subsequent attack of influenza this patient had a rather profuse uterine hemorrhage. This certainly is corroborative evidence for the assumption that the metrorrhagia in influenza patients is directly due to endometrial lesions and not ascribable to abnormal ovarian function. Unfortunately, but little laboratory work has been done on these local uterine processes. In the gravid uterus Lwow[29] was able to find decidual hemorrhages an extremely important observation, because these hemorrhages in the decidua seem analagous to those of the hemorrhagic lung. The deduction seems justifiable that a septicemic condition which produces hemorrhagic lesions in the lung likewise may react on the smaller blood vessels of the gravid uterus, and thus be responsible for these hemorrhages in the decidua. If this etiologic relation of local hemorrhage to the general septicemia exists, then it may be expected that the cases of hemorrhagic pulmonary involvement will show also a greater frequency of decidual hemorrhage. This assumption is confirmed by statistics. Harris, as previously stated, reports that pregnancy was interrupted in 26.3 per cent of uncomplicated and 51.6 per cent of complicated cases.

Deductions from Bacterial Flora

Some deductions concerning the intrauterine bacterial flora can be made from the bacteria found in the vagina. Thaler and Zuckerman[30] discov-

ered influenza bacilli in the vagina. The presence of streptococci, staphylococci, and other organisms in the vagina have been recorded.[31]

Nurnberger[32] found bacteria in the uterus in all influenza cases, chiefly long chains of streptococci in pure culture, and occasionally pneumococci, or a mixed flora. However, streptococci may be seen in the lochia of puerperal cases, at first, without rise of temperature.[33] Hintze[34] reports several cases of post-influenzal infectious processes of the genital tract involving the parametrium and the peritoneum. Zweifel[35] believes that in the presence of a systemic influenza infection, the streptococcic infection of the uterus is only a secondary process, possibly due to an injury of the endometrium by the general infective agent. Doederlein[36] even doubts that the genital organs can remain germ-free in any case of severe general infection. Nurnberger points out two possible explanations for the presence of the bacteria found by him in the puerperal uterus:

1. That a change in the mucosa, probably produced by the influenzal poison, favors the growth of bacteria ascending from the vagina.
2. That the uterine infection is hematogenous, carried from other parts of the body by the blood stream to the uterine cavity.

He emphasizes the fact that a secondary localization of the infection in the genitals has been observed also in erysipelas, furunculosis, purulent otitis media, mastitis, and especially tonsillitis; but that, in general, the ascension of the organism from the lower genital tract (vagina) up to the uterus is the more satisfactory explanation for the presence of these bacteria in the uterus.

Causes of Interruption of Pregnancy

The frequency of premature termination of pregnancy has alreay been mentioned. More will have to be said concerning the causes of this occurrence. Opinions are diverse and contradictory. Hintze and Ameiss place responsibility on either a high temperature, severe cough, or infection. Farrar believes that in the early months a hemorrhage occurs into the ovum, causing its expulsion; while in the later months the toxins affect either the decidua or the fetus directly, causing its death followed by its expulsion. In the opinion of Calderon the toxins act directly upon the uterus, inciting contractions. Lwow's important observation of hemorrhages into the decidua already has been mentioned. Such hemorrhages in the serotina, obviously will disturb the foetal circulation and tend to separate the ovum from the uterine wall.

The general conclusion would be that the more virulent type of cases would more likely develop a hemorrhage into the mucosa of the uterus, and so more frequently would show early terminations of pregnancy. A lesser degree of virulency may permit the pregnancy to proceed to its normal end, or at least until after the height of the attack. Under these conditions, obviously the outcome for the patient will be more favorable. On the other hand, the infection in some instances may so overwhelm the patient that death ensues before pregnancy is interrupted by the virulency of the attack.

The Effect on Labor

A similar diversity of opinion exists in regard to the effect of the influenza infection on labor. Bland has not noticed any unusual features during the progress of labor. Ameiss and Farrar, on the other hand, believe that labor becomes tedious due to a tendency to uterine inertia. Kosmak and Woolston and Conley think that labor in these patients is rather rapid and easy. Welz emphasizes the reduced sensitiveness to pain from the uterine contractions. Many of the patients are in a stupor as a result of the intoxication and show certain phases of amnesia. The very difference in the observations of the various writers increases the probability that as a whole labor does not vary markedly from the normal.

Puerperium and Post-Abortive Conditions

A tendency to retain the after-birth has been recorded.[6] The bleeding is prolonged and involution of the uterus arrested during the period of fever.[37] Foul odor of lochia, and subinvolution of the uterus have been mentioned.[34] It seems probable that the subsequent hemorrhage, the character of lochia and involution, to some extent, are dependent upon the localization and severity of the infection. Also, in this respect a certain analogy with the restoration of the affected lung tissue can be seen.

Condition of New-Born

Holt[38] is of the opinion that young infants are immune to the infection. Jacobi[39] never saw a child less than one year of age suffering from influenza. On the other hand, Townsend[40] re-

ports a case of congenital influenza in a two weeks premature infant. The maternal influenza commenced one week previous to labor. Both mother and child recovered from the attack. Also, Woolston and Conley mention two cases of bronchopneumonia developing eighteen to twenty-four hours after birth, in infants of mothers suffering from influenza. Abt[41] describes a two weeks premature infant born about thirty hours after onset of an uncomplicated influenza. The child died on the third day of life with marked symptoms of bronchopneumonia and the necropsy showed a streptococcic septicemia. Moeller believes that a light form of influenza occurs in practically all new-born infants of mothers affected by the disease. A better understanding of the effect of influenza on both the pregnant mother and the newborn child can be obtained by comparison with other infectious and contagious diseases which show some resemblance to influenza. Measles, ordinarily a mild disease of childhood with unknown etiology, shows a marked increase of mortality when affecting the pregnant woman. De Lee places the maternal mortality of measles at 15 per cent and Esch[42] at 18 per cent. The latter reports a fetal mortality of 52.4 per cent, and emphasizes that 72 per cent of children born during a measle attack of the mother, either exhibit the symptoms of the disease or develop them shortly thereafter. He believes that the remaining 28 per cent of these infants which did not develop measles, either had become immunized before birth or were protected by the impermeability of the placenta. In typhoid fever, pregnancy terminates prematurely in about two-thirds of cases, especially in the early months.[31] Fetal death is a frequent occurrence and is due to a direct transmission of the typhoid bacillus into fetal circulation, and the fetus is overcome by a typhoid septicemia.[43]

Condition of Placenta

The placenta shows no gross placental changes.[6] Very little has been reported on the microscopic picture of this tissue.

Treatment of the Infection

It is beyond the scope of this review to discuss the general treatment of this infection and we shall limit ourselves to special therapeutic problems offered by the pregnant woman. The usual hygienic measures, fresh air, nourishing food, and early and complete rest in bed, seemingly aid the pregnant woman in combating the infection. By themselves, however, such measures prove insufficient. The septicemia frequently overwhelms the individual in spite of these precautions.

The specific serum treatment of influenza obviously will not be developed until the offending organism is definitely established.

In view of the evident fact that a simple uncomplicated influenza does not greatly endanger the pregnant woman, we can safely recommend that such cases be permitted to pursue their natural course. In cases of severe type, especially in early pregnancy, abortion will probably occur in spite of all efforts. Medicinal treatment offers no hope in the attempt to avoid the abortion. Induced abortions or labors produced in the interest of the mother will not improve but rather tend to aggravate the general condition of the patient.[3] Norris[44] reports two cases of simple influenza with pronounced toxemia of pregnancy on whom he induced labor on account of the latter condition. Both patients recovered, but he counsels against this procedure as a routine in influenza in view of the frequency with which these uteri become infected. As previously stated, this fact is generally recognized and contraindicates all vaginal manipulations in pregnant women suffering from influenza. Obstetricians are divided in their views concerning the management of pregnant women in the presence of an influenza pneumonia. The majority of authors advocate conservatism and only a few favor interference with the further progress of pregnancy. In the view of De Lee, Kosmak, Farrar, Welz, and many others, artificial interruption has a tendency to increase the maternal mortality. Koblanck[45] is sure that emptying of the uterus does not improve the maternal chances and Welz considers all efforts to even hasten delivery as harmful. Bumm[46] reports a vaginal Cesarean section performed in a case of influenzal pneumonia with marked dyspnea and cyanosis. A premature fetus was removed. He believes that the beneficial influence of such an operation is due to the loss of blood and the relief of the pressure against the lungs by the enlarged uterus. Strassman,[47] for these same reasons, considers immediate emptying of the uterus indicated in pneumonia cases. Another observation recorded by Heppner[48] may be mentioned in this connection more as a curiosity. He performed an abdominal Cesarean section immediately after the patient had died of a

bronchopneumonia. He recovered a premature living child, which, however, twenty-five days later died of a croupous pneumonia.

In the light of all available information, briefly outlined in the foregoing pages, but a few definite conclusions are permissible.

Pregnant women more often than non-pregnant women develop pulmonary complications in the course of an influenza infection. A concurrent pregnancy undeniably increases markedly the already high mortality of influenza pneumonia. Therefore, influenza represents a very serious disease for the pregnant woman. A co-existing pregnancy requires no particular change in the customary medicinal and hygienic-dietetic treatment of the disease. Spontaneous abortions, especially early in pregnancy, are likely to occur; but the spontaneous expulsion of the uterine contents in any stage of pregnancy does not noticeably alter the chances of the mother. This can not be surprising. The most careful studies in the possible relation of influenzal infection to the uterus seem strongly to support the assumption that local uterine lesions, developing secondarily as the result of the general toxemia or septicemia in the severer cases, in the main are the cause for the premature expulsion of the uterine contents. Therefore, but little could be expected from artificial interruption as a therapeutic measure, suggested by some writers. The desired beneficial result for the mother through relief of pressure against the diaphragm and through loss of blood, probably is more than outweighed by the unavoidable untoward effect of any operation performed on a very seriously sick patient, and by the increased danger of uterine septic infection. It is important to remember that an improvement of the mother's condition has been noticed chiefly in those cases in which the spontaneous expulsion of the fetus occurred after the mother had passed the crisis. Any artificial interruption obviously would be instituted before that time, *i.e.*, in a period of the pneumonia when even spontaneous labor seemed to aggravate the condition.

IMPROVES RURAL HEALTH ADMINISTRATION

A campaign financed jointly by Federal, state and local authorities is being conducted throughout the state of Virginia with the purpose of improving health administration in the rural districts.

MEDICAL BENEFITS UNDER COMPENSATION LAWS

The following tabular statement published by the United States Bureau of Labor Statistics shows briefly the maximum medical benefits provided under the various compensation laws:

It will be noted that three states—Alaska, Arizona, and New Hampshire—furnish no medical service except that in fatal cases involving no dependents the expenses of last sickness shall be paid by the employer. Six compensation acts provide unlimited service. Nine laws place no limitation upon the period during which treatment shall be furnished, but do limit the amount; while nine limit the period, but do not limit the amount. All of the other laws place limitations upon both period and amount.

MAXIMUM PERIODS AND AMOUNTS OF MEDICAL SERVICE UNDER VARIOUS COMPENSATION LAWS.

State	Maximum period	Maximum amount	State	Maximum period	Maximum amount
Alabama	60 days	$100	New Jersey	4 weeks [1]	[1] $50
Alaska			New Mexico	2 weeks	$50
Arizona			New York	60 days [1]	Unlimited.
California	Unlimited	Unlimited.	North Dakota	Unlimited	do.
Colorado	60 days	$200	Ohio	do.	[1] $200
Connecticut	Unlimited	Unlimited.	Oklahoma	60 days [1]	[1] $100
Delaware	2 weeks	$75	Oregon	Unlimited	[1] $250
Hawaii	Unlimited	$150	Pennsylvania	30 days	[1] $100
Idaho	do.	Unlimited.	Porto Rico	Unlimited	Unlimited.
Illinois	8 weeks [1]	[1] $200	Rhode Island	4 weeks	do.
Indiana	30 days [1]	Unlimited.	South Dakota	12 weeks	$150
Iowa	4 weeks	[1] $100	Tennessee	30 days	$100
Kansas	50 days	$150	Texas	2 weeks [1]	Unlimited.
Kentucky	90 days	$100	Utah	Unlimited	$500
Louisiana	Unlimited	$150	Vermont	2 weeks	$100
Maine	30 days [1]	[1] $100	Virginia	30 days	Unlimited.
Maryland	Unlimited	$150	Washington	Unlimited [2]	do [2]
Massachusetts	2 weeks [1]	Unlimited.	West Virginia	Unlimited	$600
Michigan	90 days	do.	Wisconsin	90 days [1]	Unlimited.
Minnesota	do [1]	[1] $100	Wyoming	Unlimited	$100
Missouri	8 weeks	$200	United States	do.	Unlimited.

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

FEWER FREE HOSPITAL PATIENTS

THE fortieth annual report of the United Hospital Fund of New York, as analyzed by the *New York Times*, indicates a decrease of 16 per cent in the proportion of hospital patients receiving free treatment in the last eight years, and in this interval the proportion of patients who pay all or part of the ward rate has increased 17 per cent. In the opinion of Frederick D. Greene, general secretary of the organization, this showing indicates that people generally are in better circumstances. It is evidence, also, that the working people are not inclined to impose on hospitals.

The United Hospital Fund began in 1879 with nineteen hospitals, caring for 8,688 patients during the year, with receipts amounting to $26,455.07. During the past year the organization gave support to forty-six hospitals, caring for 147,422 patients and giving 2,443,562 days' treatment, and the receipts amounted to $221,535.34. The service rendered by the organization, however, is not to be measured solely by the number of patients cared for. It has been of inestimable service to hospitals and to the public in the promotion of accurate hospital statistics, and in securing a uniformity of records which permit intelligent comparison.

The Hospital Fund finds that there are 180,000 people, on the average, who are sick in New York every day. It is estimated that only one in ten of those who need hospital care get it. "Moreover," says the report, "32 per cent of our young men were rejected as unfit for the army—16 per cent for serious, and 16 per cent for minor defects. As this ratio is true of us all, it means that at least one million people in New York City have serious ailments and another million labor under lesser handicaps. . . . The need of hospital care is far beyond hospital facilities, and it is imperative that there be wise hospital planning for the whole city, and the largest return for every dollar spent."

It is now costing about $9,500,000 a year to maintain and operate the forty-six United Hospitals. The average cost per day for ward patients last year was $2.69, against $2.06 per day two years ago, an increase of 30 per cent.

The cost of the ward patients in the forty-six hospitals of the United Hospital Fund is:

HOSPITALS Arranged According to Cost of Ward Patients	Daily Cost Ward Patients	Daily Patients	Census Employees	Percent Beds Used Daily
Above $4 a day—				
Ophthalmic	$6.34	19	16	25

INDUSTRIAL MEDICINE

By NORMAN BARNESBY, M D., Consultant, Letchworth Village, Westchester County and St. Bartholomew's Hospitals, New York City

Industrial medicine is interpreting the productive capacity of the plant in terms of the health of the workers.

Medicine in industry is as much a department of practical utility as any other part of the organization, and strict cost accounting of medical service but serves to emphasize its benefits.

The education of the industrial group in health matters reacts to the good of the community. With a widespread realization of its paramount importance, health will become the objective of intelligent cooperative effort, and increased energy, better mental attitudes, and disseminated knowledge will make it universal.

TWENTY years ago there were few medical directors of the large industries. There were fewer still of the large corporations. There were none who filled the capacity of medical director in its present-day significance. The value of industrial medicine was unknown. Moreover, the organized supervision of the health of employees was a field of science unexplored if not undiscovered. Applicants for jobs were accepted usually without physical examination. The honesty, sobriety, cleanliness of habits,—the health of the applicant, qualities vital to the interest of the employer, had to be determined by the applicant's appearance at the time of the interview. For years we have been confronted with countless articles about "reading faces." It is an art upon which a great deal of responsibility must be placed, and yet it is undependable unless fundamentally supported by reliable investigation of a purely scientific nature.

Physical Examination Essential

Physical examination of applicants is, of course, only a small part of the field of industrial medicine; but its value is apparent. For example, at the present time about 3 per cent of applicants for jobs in the big industries are turned down on account of physical disqualifications. Of those who are accepted much is learned about their habits and mode of life which is of the utmost interest to the medical director. In case of sickness the doctor has on record an account of the physical and mental characteristics of the patient that is of intrinsic value to him in making his diagnosis and in determining the treatment. Physical examination of applicants was one of the first needs for medical advice felt by an employer of factory hands or of any laborers to whom good physical stamina is of paramount necessity in the retention of their jobs.

The development of industrial medicine has been exceptionally rapid. It had to grow with the industries of which it formed a part. Just as there have been the two forces of mechanical engineering and chemistry which have impelled the rushing progress of industry, there have been four main factors which have been the material causes for the rapid development of industrial medicine and have made it keep pace with industry. These four factors are (1) accidents, which occur especially in factories; (2) tuberculosis; (3) the public health campaign carried on by the government and other agencies; and (4) labor difficulties.

In a great many industries, more than 20 per cent of the employees formerly met with an appreciably serious accident each year. The United States Steel Corporation was one of the first industries to realize what this ever-increasing number of accidents and injuries to employees was costing them. Their business is one that presents a certain degree of risk to their employees. First aid hospitals had been established at the outset. As the corporation grew and accidents increased, the hospital system was enlarged—proportionately. "Safety first" campaigns were waged with volumes of literature and numerous rules; and a complete medical supervision over the health of the employees resulted. Of many other industries in which hazardous work necessitated continuous watchfulness against accidents, this same story may be told.

Tuberculosis a Factor

Fifteen years ago tuberculosis was the disease most prevalent in the United States. The tubercle bacillus threatened the efficiency of all business, and at one time the prosperity, if not the life of the country. That little germ might bring about degeneration of society, might sap the vitality of a nation, causing its civilization to decay and its children to deteriorate. Such morbid reports as these were circulated freely. Everyone was alarmed. A cure was found, but the cure

necessitated immediate discovery of the disease, and in this case the exigency of periodical examinations of employees was brought home to the employers of shop girls, office clerks, and other indoor workers in the large cities. Department stores and corporations followed the example of the factories, and here, again, there resulted skillfully organized medical supervision.

The third factor in the development of industrial medicine arose in the public health campaign, in which state governments, city boards of health, and the Federal Government vie with one another in the effort to stamp out disease. As a result we find a general betterment of living conditions, and a marked improvement in working conditions. We find rest rooms and play grounds provided in the large corporations and in factories. Child labor is prohibited. Working hours are limited. Reformation is general and widespread. Such an influence was bound to permeate all large industries. Employers began to see the benefit obtained by industrial medicine in promoting the efficient conduct of their business. That legislatures noted the benefit of industrial medicine to the voting class is evidenced by the fact that Massachusetts has been busy of late putting into effect the provisions of an amendment of the state labor laws enacted in 1918 requiring every employer employing over one hundred persons to provide facilities for the treatment of persons injured or taken ill on the premises and, also, suitable and sanitary installation for heating or warming food to be consumed by the employee.[1]

The fourth, and the most recent cause for the thorough centralization of previously elemental experiment with the medical department of a corporation, which scarcely could have been called industrial medicine, is the difficulty of cooperation between the capital and labor classes. The various employers are attempting to placate labor in some way that will not spell the financial ruin of their companies. The first experimentation in this line took place in Germany before the war in their various plans of insurance. The argument for group insurance is based mainly upon this idea of keeping employees satisfied, in that it provides the cheapest possible way for an employer to give money to his employees. Industrial medicine is health insurance. Slightly different from all other forms of insurance which pay the individual something in compensation for injury he has received or damage done to his property, health insurance endeavors to prevent accidents and sickness by keeping the individual in the best possible physical condition, and by checking at onset any sickness which might develop later into something more serious. For this reason it may be said to be the most potentially valuable attempt to bring about cooperation between capital and labor. It is apparent that labor is not to be convinced by argument of facts that it would be impossible to concede to their demands. The only other way is to keep labor from making these impossible demands; and maintaining a man and his family in good health accomplishes much toward keeping him satisfied. If there is any way to make an employee feel some appreciation for what is done for him, it is to cure him or his wife or child of a disease. More and more are employers beginning to understand this.

1. Am Jour. Pub. Health, October, 1919, p. 807.

Industrial Medicine Defined

The question "Why do employers institute medical departments?" or "What are the benefits to employer and employee of a thoroughly equipped and organized medical department?" will be referred to later. Here we have simply sketched a history of the development of industrial medicine, recalling the four main causes for its rapid development. The question naturally presents itself as to exactly what is industrial medicine in the present significance of the term.

Passively, industrial medicine is the science of medicine in its relation to industry; actively, it includes the many functions of the modern medical department of a large corporation. The physical examination of applicants has already been mentioned. By thorough examination of applicants the doctor is able to discover any existing defects. For instance, in the case of heart disease, an applicant will either be placed in a position which will not be detrimental to his health, or he will not be accepted at all. With the record of a physical examination on file, the doctor has a knowledge that will make him appreciate more fully any ailment a man may display when injury or sickness brings him to the hospital. The function of a medical department is primarily prevention of sickness, not cure; but, of course, the curing of some minor disability can often remove the direct cause of an illness more serious. Every employee of a large corporation with an adequate medical department is urged to come often to the hospital for examination. The efficiency of the medical organization depends not a little upon the desire of employees to keep the doctors informed of their state of health. Often, in the case of a man with some minor defect, a slight change of work, of mode of living, of diet, or of medicine, may increase his capacity to that of the normal man.

Much sickness can be prevented by good advice. Fatuous quacks with thick rimmed spec-

tacles, a shining array of instruments, and a patented supply of pulmo-gastric data, still fawn over the sick bed and apply soothing syrups and soft sentences to a broken leg with the inane blandness of a superlative jackass. And people hearken to these men and pay them for their soothing syrups, so that they can buy some more and give it to the next patient. A medical department issues its advice through the medium of literature in pamphlet form as well as through the treatment of patients. Advice on almost every known disease is thus circulated. Such pamphlets contain information about the eyes, the teeth, blood poisoning, indigestion, strains, or colds, and they warn people against the unctuous syrup-perfumed quacks, and explain the medical science as a whole in a way that make the reader think. To make people think is a great service to mankind.

Medicine Essential to Industry

Today the medical department is a vital part of the machinery of a corporation. In twenty years the population of lower New York during working hours has increased from several hundred thousand to about two million. Mill and factory cities have sprung up everywhere. Society is crowded, especially during working hours. They have had their doctors at home; they must now have them while at work; for it is a well recognized fact that industrial medicine is an efficiency saving device, that it is an institution worth while to employer and employee alike. Moreover, it is apparent that it promotes efficiency. A man who previously would go home with a headache now gets relief from the medical department and works while he is being cured. The employee gets medical attention and often surgical attention, free for himself if not for his wife and child. Disability diminishes, and sickness is prevented. Stricter account is kept of employees, and a man's character, mode of living, and habits are better known to the employer. Just how much worth while it is, from a financial standpoint and in regard to efficiency, is a question that would involve a comparison of the cost of maintaining a thoroughly organized medical department with the cost of the labor lost through sickness or injury previous to the organization of the medical department; and figures on the latter part of this question are obtained with difficulty.

In my own experience no record of employees leaving work on account of sickness was kept until the medical departments were organized. There is no way to tell how much sickness had cost the National City Bank, or the National Bank of Commerce, or the American International Corporation prior to their provision of medical service. Furthermore, inquiry showed that the same thing is true of many other corporations. I finally obtained statistics from a large industry in Worcester, Mass. This firm now has a large hospital and an excellently organized medical department. A comparison of records showed them that medical supervision saved them 19.2 hours per man per month. Assuming an extremely conservative average wage at one hundred dollars a month, this would effect a saving of about ten dollars worth of work a month per man, or $120 a year per man. According to the July, 1919, issue of the *Monthly Labor Review*, in which figures have been compiled from the experience of ninety-nine industrial establishments in the United States, all with a personnel of more than 1,000, the average annual cost of medical and surgical supervision per employee for these ninety-nine establishments was $2.50, or 2.08 per cent of the cost of the labor that would have been lost. In other words, through industrial medicine, it costs a firm with a thousand employees at least, about $2.08 for every one hundred dollars worth of work they would have lost without the institution of a medical department.

Comparison of Costs Difficult

A great many objections can be raised, attempting to show that such percentage would be erroneous in the case of a great many firms; but the figures are so very favorable from the point of view of the employer that no objection or comparison could show that industrial medicine is an extravagance. In such a comparison as this, there are many influences which have been necessarily disregarded. The new era of the world's history has changed and is changing conditions and ideals by making for the betterment of surroundings, shorter working hours, the expansion of all business and the rise of new industries. Quicker transportation from home to office is promoting the growth of the suburbs. The upheaval caused by the war, the reaction of reconstruction, the epidemic of influenza,—these, and many other influences as widely varied would have to be considered statistically in making an absolutely true comparison; and this, of course, would be impossible; but in the figures given, the preponderance of money saved over the cost of medical service is so great that not much argument can be raised to disprove the estimate made.

For the sake of argument, suppose the cost to be $102.08 for every $100 saved. Would not the benefits, which are not to be estimated by dollars or cents or percentages,—benefits such as educa-

tion, cooperation, general improvement of health, increase of efficiency, advance in the science of medicine,—more than balance this $2.08? This last benefit, namely, the advance in the science of medicine, may need explanation. It is the advance due to experimentation, not amateur experimentation which might be harmful, but practical professional experimentation such as the work now being undertaken by one large company today who are inoculating 1,500 employees with a serum to prevent colds. This serum is in no way harmful. It causes no inflammation such as vaccine does, or slight rise in temperature such as results from the inoculation for typhoid fever. The medical department of this company is keeping a record of these 1,500 employees with a parallel record of 1,500 employees not inoculated for the purpose of comparing results. During the epidemic of influenza this same company tried much the same experiment and found that the disease was 50 per cent less prevalent among those who had been inoculated than among those who had not received the serum treatment.

Regarding cooperation, in a study of relations between employer and employee, Grant Hamilton, director general of the Working Conditions Service of the United States Department of Labor, through Dr. William M. Leiserson, makes this report: "In proportion as the employment organization is efficiently operated, and the hiring, training, distribution, and management of employees are properly handled, there will be less need for so-called 'welfare work' to keep employees contented. Personal service work will, however, always be needed. The safety and accident prevention movement is sufficiently developed to require little more than mention here. Sanitary conditions in the factory and protection of the health of employees by industrial physicians and nurses are also plain business measures for decreasing sickness, absences, spoiled work, and for increasing production."

Economy and Safety Assured

From the point of view of the employee, industrial medicine means improvement of health, free care, education, and economy. A man, and especially a woman, feels a certain relief to know that immediate care is available in case of accident. It is a comfort to know that no prolonged illness can eat up their salary; that they will be given free care and the best care. In 1918, out of about 5,500 employees of a large corporation in New York, 5.437 persons made 29,828 visits to the company's doctors. In other words 95 per cent of the personnel made an average of five visits. They received this medical attendance free. In many cases visits for slight injuries or sickness would not have been made if the patient had had to pay for the appointment; and in many other serious cases, the patients would have had to spend some appreciable amount to be cured by their own doctor. The only possible comparison would show that at an average charge of $1.75 per visit, the average savings per employee for medical care would be about $8.75. This means that many employees were cured and retained their positions who previously would have had to resign their positions because of sickness which they could not themselves afford to cure.

Aside from its bearing on the private industry concerned, industrial medicine has a direct relation to the interests and health of the nation. Industrial medicine contributes to the stimulation of production and thus to general welfare. Figures of total daily production by the individual, from day to day and week to week, show unusual uniformity. Recent inferences that laborers are not doing as much as they can, and are working with some sort of idea of quantitative output as being equal to a day's work, in their minds, seems to be justified. From the point of view of industrial medicine each employee is a mechanism, more intricate than any other mechanism because it is human. It is the part of industrial medicine to keep this mechanism in the best working order, to have this machinery run more and more smoothly. Mechanical engineering and chemistry have caused the phenomenal industrial progress of the last two decades, but the human side has not been eliminated. Men and women are more necessary than ever to carry on the work of the industries. Thus industrial medicine can be regarded as another science, necessary to the practical application of engineering and chemistry. Perhaps its present greatest utility is education. Sound education will lessen bad influence. Education which in this case, inherently infers decent surroundings, is the only method yet discovered to change a man's state of mind toward his work, and a change in the state of mind of workers toward their work, is particularly necessary at this time if industries and government are to exist.

Contributes to National Welfare

Another result of industrial medicine, already noticeable, is the betterment of national health. To read about the activities of this and that board of health, this doctor and that medical director, in the fight against disease, may lead one to think that there is little existent contagious disease or few serious defects in the average men on the street. The Department of Health of the City of New York recently examined 1,500 male

and 390 female foods handlers, including waiters, waitresses, cooks, and bakers. They found only 511 men and 52 women without disease or defect, and as many as 2,842 types of disease and defect, which indicates a serious situation, the systematic improvement of which is entirely problematical.

It is not that these waiters and waitresses and workers in general do not desire to be cured, but they cannot afford to be cured by a private physician and they shun the idea of the subsidized hospital or the clinic. There is so much absolutely unregulated, uncontrolled, unorganized, unintelligent, unrecognized, unknown sickness subsidy throughout the country that such a situation as now obtains is the normal result. Workers who have no medical department connected with the concern they work for are driven to the free wards, where they either form such a prejudice against doctors and medical science as a whole that they never return, or they get hospitalized to such an extent that they become hypochondriacs. Moreover, this free medical care in the shape of clinics and almshouses and free wards is bestowed upon workers as the benevolent regard of a philanthropic society, not given to them as what is most justly, or rather unjustly, theirs. This does not mean that our system of sickness subsidies should be abolished nor does it advocate socialization of medical attendance; but certain defects and faults in our present system should be rectified and I mean that industrial medicine should play its part in an early readjustment of the system. Furthermore, there must be an expansion of industrial medicine, an expansion so great that it will materially lessen the number of workers driven by necessity to the free wards. That employers cannot evade this issue by handing out a sickness gratuity is too obvious to require explanation. Moreover, the worker must be held somewhat responsible for his own health and the health of his family, and must pay a share. A system of universal sickness and health insurance must be substituted,—a cooperative system in the organization of which industrial medicine will form a vital part.

Health Boards and Industry

Industrial medicine is closely connected with the state and municipal boards of health. Medical directors and assistant medical directors are frequently called by the mayor or governor to give advice or statistics. Cooperation in the medical line between public and private interest is becoming more and more thorough. It may be said the term "private interest" should not be used in connection with industrial medicine because industrial medicine is perhaps more intimately connected with the public than are the boards of health themselves, and may become more intimately connected with the public,—the working class of the public—than the free wards and the clinics. The Board of Health makes rules to prevent disease; industrial medicine goes further, and cures disease. Industrial nurses visit the sick. Industrial doctors cure the sick, and take into account those with slight ailments. Workers are not driven to them by dire necessity. It follows that, regardless of the material advantages, industrial medicine presents to employers and employees alike advantages which assure its rapid expansion, and it is directly and indirectly doing the nation a great service. Its influence reaches millions of people. It teaches them to think. It educates them. It comforts them. It insures better health, better hiring and working conditions. It helps to stamp out epidemics. It stimulates efficiency and production. It gains experience for the science of medicine. It organizes and centralizes the cure of the sick and the prevention of disease. It is a link between capital and labor. The solution of the most acute problems of these times is left to it. It is a new science, a new industry in itself. That it will expand and will become more and more efficiently organized is certain; but its problems are many, and it must attain the highest pitch of efficiency and cooperation with other medical institutions to solve them.

FORMULATION OF NEW SAFETY CODES

The formulation of codes on safety in paper and pulp manufacture and safety in blast furnaces operation was tentatively assigned to the National Safety Council by the National Safety Code Committee at a recent meeting held in Washington, D. C.

The Committee—which consists of representatives of the National Safety Council, the Bureau of Standards, the Safety Institute of America, the American Society of Mechanical Engineers, the National Electric Light Association, the stock and mutual insurance interests, underwriters' laboratories, and the state industrial commissions of New York, New Jersey, Pennsylvania, Ohio, Wisconsin, and California—also suggested that the National Safety Council undertake the formulation of safety codes on building construction and on power presses. This will be done by the Council through its construction and engineering sections and with the assistance of other interested organizations.

The National Safety Council has prepared for its own membership safe practices pamphlets on paper and pulp manufacture, blast furnace, and power presses and it is probable that the standards formulated for distribution to industry at large through the National Safety Committee will be based on the safe practices pamphlets already issued by the National Safety Council.

The mining section of the Council was asked to take up with the Bureau of Mines and the mining societies the matter of formulating mining safety standards in addition to those formulated by the Bureau of Mines.

WAR CONTRIBUTIONS TO INDUSTRIAL SURGERY*

By STANLEY R. MAXEINER, M.D., Minneapolis, Minn.

The physician-soldier has learned his lesson and, like the true scientist he is, has measured the results of his war work and seeks to apply them to civil problems.

Whatever has contributed to the safe and expeditious handling of war cripples and the earliest and most complete possible restoration to service should become a part of the equipment of the industrial surgeon.

For the true value of a method is not its application in a limited number of cases, but the successful outcome it achieves as an accepted procedure, and the chief war contribution to surgery will be in the selection of methods proved by the acid test of wide observation of end results.

DURING the past ten years there has been developing in the medical profession a new group of specialists—the industrial physicians and surgeons. Today industrial medicine has reached the highest point yet attained, and is gradually subdividing itself into its natural branches. It is perhaps only natural that this branch of the profession should reach its greatest height at this time, for this is truly an industrial era, a day of organization, and of group thought and effort. Its rapid development is due to the demands of organization, both of labor and capital, rather than to any conscious effort on the part of our profession. The Workmen's Compensation acts and the proposed new laws on health insurance are expressions of concerted effort on the part of others to secure better health measures. It is time for the medical profession, through better organization and greater effort, to concern themselves with these measures relating to hygiene, sanitation, prevention of disease, precaution against accidents, matters of over-work, and the problems of fatigue; for surely with their knowledge and familiarity of the subject, physicians are best capable of judging and suggesting what policy to pursue. Geier in Modern Medicine for November calls attention to the fact that on the National Industrial Conference representing many branches of industry, several professions, and numerous labor groups, the president failed to appoint a single physician. This new branch of medicine may help to bring about a closer bond between the physician and the employed, and between the physician and the employer. He may even be the means of bringing the two groups together.

In this paper we shall pass over the lessons gained from the war which may apply to the industrial physician and limit the discussion to those of particular interest to the industrial surgeon. The conclusions are based on a review of the literature and the author's personal experience and observation while serving for twenty-two months with the British Army as Battalion Medical Officer, Medical Officer attached to Field Ambulance, surgeon at a war hospital in London, and as radiologist and surgeon at a Casualty Clearing Station.

The Procedure in Shock

A large number of wounded soldiers suffered this complication because they were often extremely fatigued, under-fed, deprived of water, and frequently suffered severely from exposure to cold at the time of injury. Every effort was made at every relay from the front line to the advanced hospital to combat this condition. In the dressing stations the soldier in shock was placed in blankets on a stretcher suspended over oil stoves and, while his wounds were being dressed and splints carefully applied, he was given hot drinks or perhaps hypodermic salines. At the casualty clearing station it was found very early that if these cases were operated upon at once the mortality was very high. During the necessary delay he was put in a resuscitation ward and further treatment instituted. Absolute rest was imposed and more heat applied. Fluids were given by mouth, per rectum, hypodermically, or into a vein. It was remarkable how quickly these cases responded to transfusion of blood whether there had been hemorrhage or not. The patient was grouped at once and a proper donor, who was always on hand, furnished 500 to 1,000 cc. of blood.

We used many methods of transfusion, but eventually adopted in our hospital the following technic which is described because of its simplicity and efficiency: 500 to 1,000 cc. graduate glass rod; large needle with very clean lumen; 2 per cent sodium citrate; 500 to 1,000 cc. of sterile salt solution; funnel, rubber tube; and second needle. The large, clean needle, pointed distally, is introduced into a vein in the arm of the donor and the desired amount of blood al-

*Read before the Hennepin County Medical Society, Minneapolis, Minn., January 14, 1920.

lowed to run into the graduate containing a requisite quantity of sodium citrate solution to make a .2 per cent solution with the blood. Both are steadily mixed with the glass rod. The citrated blood is then introduced by means of the funnel, tube, and second needle into a vein of the patient. The blood may be preceded or succeeded, if desired, by additional salt solution, intravenously. This method is so simple that we have of late in civil practice performed transfusions in the patient's bed as was our custom in France. At the front we often had citrated blood in sterile flasks kept on hand for use in an emergency. A most important factor regarding transfusions is not to wait too long, but to act before the patient is *in extremis*. Gum Acacia solution, so often recommended as an improvement over plain salt solution, was in our experience, no better; on the contrary, three fatalities occurring in less than an hour after infusions we felt were directly attributable to the use of this solution.

The Inter-Allied Surgical Congress expressed the opinion that the best treatment for shock is rest, warmth, morphin for pain, fluids, and blood transfusion.

The Treatment of Wounds

Early in the war a source of great wastage of man power was found to be due to the improper care of the slightly wounded. Numerous cases that should have been returned to duty in a few days developed complications which caused a protracted convalescence or even complete permanent disability. Similar cases are only too numerous in industrial accidents.

The first principle of the treatment of wounds founded on the technic used in war surgery is based on the fact that early wounds are contaminated but not infected. When a *débridement* is done, all contaminated and devitalized tissues are excised; the devitalization being determined by the reaction of the tissue to a mechanical stimulus and whether or not it bleeds. Foreign bodies are removed and from 80 to 90 per cent of all wounds so treated may be closed primarily. If it is not considered advisable to do a primary suture, the wound may be packed widely open with gauze and in seventy-two hours a delayed primary suture done. This was usually the time also of the first dressing. Some surgeons chose to institute irrigations every two hours with Dakin's solution during the three-day interval in place of the dry gauze pack. It is to be noted that the more experienced the surgeon, the more thorough and complete was the *débridement*, and the more successful were the primary sutures. By this form of treatment many cases of compound fractures were converted at once into simple fractures, abdomens were less often drained, and wounds into joints were invariably closed primarily. Cuthbert Wallace reports 625 primary sutures with 444 successes; 69 had some union; 69 were failures. In one series of 100 compound fractures, 75 per cent were closed primarily with success. Approximately 50 per cent of all wounded were treated by primary suture.

When wounds became septic, Dakin treatment was usually instituted at once. In our hospital in place of the glass manifold tube connecting the many rubber tubes, it was found to be an advantage to leave the ends of the tubes protruding from the first dressing and to irrigate each tube individually. This procedure, though somewhat more time-consuming, insured that each tube was functioning, and that all the solution was not running through one tube. Another feature essential to success in the Dakin treatment is the necessity of standardized solutions. Many of these wounds with proper treatment soon had bacterial counts sufficiently low and presented a clinical appearance suitable to permit closure by secondary suture or by skin grafting. When grafting skin from one individual to another, it is now generally accepted that they should be grouped the same as for blood transfusion.

The Use of Antitetanic Serum

In the British Army it was ordered that antitetanic serum should be used in all cases in which the skin surface was broken and in cases of Trench feet. This may seem to be over-doing it a bit in civil surgery, but we do not use it often enough and it is our opinion that the courts will eventually hold that the man who failed to use antitetanic serum as a prophylactic measure in a case of tetanus is both neglectful and liable. Antitetanic serum was given as an initial dose of 1,500 units or in three doses of 500 units each at weekly intervals. The latter method seemed to render better protection against the so-called case of delayed tetanus.

The great advance made in this particular subject should be of special interest to every industrial surgeon. Considering every compound fracture a contaminated case, a thorough mechanical cleansing, that is, *débridement* is indicated. Depending on the extent of the injury, the wound may be closed by primary or by delayed primary suture and the compound fracture converted into a simple one. If this procedure meets with success, the functional result is thereby greatly improved, period of disability often cut in two, and the patient saved many hardships.

Fracture of the femur was one of the greatest problems of the war and deserves special attention. In 1914 and 1915 most of the fractures of this type were transported with the long Liston splint. All arrived at the casualty clearing station in deep shock and the mortality was very high indeed, ranging from 40 to 50 per cent. Later, in 1916-1917, the Thomas outfit was generally adopted and applied by the Regimental Medical Officer or trained orderlies and stretcher bearers on the field. These cases then arrived in much better condition, due principally to the improved methods of transportation, so that the mortality rate was reduced in 1918 in the British Army to about 30 per cent.

All emergency ambulances should be equipped with the Thomas outfit and attendants should be thoroughly instructed in its application. We would also strongly recommend that the outfit be placed on trains, in dispensaries connected with large industries so that surgeons who are called upon to treat such injuries have access to it, and that all cases to be transported be so dressed. This would apply very well to the country practitioner who wishes to send such a case to the city for treatment.

Treatment by Extension

Treatment by extension in the case of fracture of the lower extremity was quite generally accepted by all of our Allies. The use of the calipers and Stenman pin is a great advance in hospital treatment when extension is desired, while the Sinclair glue with gauze is a great improvement over the old adhesive strapping.

Formula

Glue	49
Thymol	1
Cal. Chlor.	1
Aqua	50

During the March retreat near Albert, the author personally evacuated 248 wounded cases and put up eight fractured femurs with the Thomas outfit in twenty-four hours.

Massage and early passive motion are essential to an early restoration of function. Splints adjusted and constructed to permit the passive motion of joints contiguous to a fracture from the first day have been devised and successfully used by Blake. Many cases thus treated have a complete range of motion of the limb when the fracture is healed. This should be of value in the conservation of man power by greatly shortening the period of disability in fracture cases.

The x-ray is as indispensable in this group of cases as in the removal of foreign bodies, both from the standpoint of diagnosis and treatment. The portable x-ray machine which obviated the necessity of moving patients from their beds was of great value in the treatment of fractures.

During almost ten months service as radiologist at a casualty clearing station I found that a surgeon did not want to know how many centimeters a foreign body was below the surface, for measurements convey little to his mind when he is under the stress of an operation. He did want marks on the skin with the part in the normal position of rest in which all localizations were made. An "X" was made above and below the foreign body with indelible ink, and the depth recorded laterally on the part by a straight line through a circle. The approximate size, together with its relation to important structures, was also reported; *i.e.*, whether it lay in front of or behind the femur or interosseous membrane, or in the bone, in the abdominal wall, or whether it penetrated into or through the abdominal cavity; whether it had lodged in the chest wall or had penetrated the lung. In the chest and abdomen the course of the foreign body, determined by the wound of entrance and its present location or wound of exit, could be traced very successfully on anatomical charts of life size.

The Wounds of Joints

The treatment of wounds of joints was almost revolutionized by war practice after a thorough mechanical cleansing of the wound and of the joint by *débridement*, the joint being often aspirated first to determine whether or not it had been penetrated, the capsule was invariably sutured without drainage and the other soft tissues closed by primary or delayed primary suture. By this method the usual stiff joint of pre-war surgery was avoided. The subsequent treatment was passive motion, started at once, no splint being applied. Frequent subsequent aspiration may be necessary.

The knee joint was the one most frequently injured. In the case of the knee, if the joint became septic following a penetrating wound, free lateral incisions were made early, irrigation with Dakin's solution and passive and active motion continued. The movement of the joint promotes drainage and literally squirts the pus out of the joint recesses. Drainage or Dakin tubes into the joint cavity are unnecessary and harmful. Secondary suture may be possible later.

In cases requiring surgery of the abdomen there have been few changes. The case received early is usually best operated on at once, but if received late, many cases do better after rest, stimulation, the application of heat, and blood transfusion. The use of one row of sutures in an intestinal

resection saved much time and, so far as the author was able to observe, proved quite ample. The ordinary base ball stitch was commonly used. Surgery of the thorax under war conditions developed many improvements both in technic and results. The long incision parallel to a rib border with wide retraction of the ribs has usually proved more satisfactory than the large flaps that sectioned the ribs. Because of its vascularity and oxygenization the lung tissue is very resistant to infection. Gaping wounds of the chest, usually called sucking wounds, cause profound shock and should be closed at once either by suture or by strapping. Hemothorax, following lung injury, requires frequent aspiration. A rapid, sudden increase of fluid in a hemothorax usually means the advent of infection. Empyema has been found to respond in many cases to irrigation with Dakin's solution by a special technic, and in many cases the routine rib resection, with its numerous objectionable features, may be avoided.

The lessons gained in the surgery of the nervous system are numerous, but one is of special note, namely that sutures of nerves following a *débridement* with primary or delayed primary suture of the wound affords a much greater prospect for a functional result than a suture done several months later when there is excessive fibrous tissue between the ends of the nerve with advanced degeneration of both nerve and muscle. Plastic and orthopedic surgery constitute a separate field.

Burns are now treated successfully and with increased comfort to the patient by paraffin applications. The pedunculated whole-skin flaps prevent excessive scar formation and give a tougher surface with better functional results than the Reverdin or Thiersch grafts.

Conclusions Regarding Anesthetics

The Inter-Allied Surgical Congress held that the anesthetic of choice is nitrous oxid-oxygen combined with local anesthesia. Surgeon General Bowlby reports the brilliant work of Captain Taylor and his anesthetist, Captain Marshall, who by this method reduced their mortality from 50 per cent in 1917 to 29 per cent in 1918 in series of 100 consecutive gunshot wounds of the abdomen. Colonel Cabbott performed 90 amputations of the thigh under ether and, later, 90 under spinal anesthesia with a reduction in the latter series of mortality of 50 per cent, while Captains Taylor and Marshall reduced their mortality for this operation more than 200 per cent with gas-oxygen and local anesthesia. Warm ether is also reported in the British statistics to be followed by fewer pulmonary complications than when given by the open method. Bowlby recommends that ether always be administered warm.

Local anesthesia alone was employed very little in the British army and, as a result, they were not so skilled in its use, but toward the close of 1918 most trephining operations were done under local anesthesia, as recommended by Cushing, and many operations on the chest were being done with satisfaction. Repeatedly, I saw ether or chloroform given to remove a foreign body that might more safely have been done with novocain.

Great schools and shops are now being operated by the Government to re-educate the soldier incapacitated for his old position. This restores him to society, a self-supporting, self-respecting citizen, dependent on no one. The problem of the industrial cripple is not only a local issue but a national one and the work of rehabilitation should be kept up in the future and made to apply to the man rendered unfit by an industrial accident. He will then no longer become a cast-off, but by re-education and training he may continue to be self-supporting.

Surgeons caring for industrial accidents should be prepared to treat fracture and joint injury cases with the same apparatus and methods used in the army in the process of re-education. Doubtless, when the present number of disabled soldiers has been cared for, attendants trained in the army technic and with large practical experience will be available for positions in institutions where such cases are treated.

Summary and Conclusions

(1) The Inter-Allied Surgical Congress has outlined definitely the most successful treatment for shock.

(2) Blood transfusions prepared wounded soldiers for extensive surgical operations and saved thousands of lives. Every hospital should have a pathologist or technician available for grouping patients and donors, already grouped should always be accessible from among its employees. Blood should be transfused before, during, or after operations on patients suffering from severe shock.

(3) More attention and better care of the slightly injured are indicated.

(4) *Débridement* should be performed on contaminated wounds of industry the same as on war wounds. Primary, delayed primary, or secondary suture should be practised extensively in an attempt to shorten the period of disability in industrial injuries.

(5) Anti-tetanic serum should be used in all industrial accident cases with abrasions of the skin.

(6) Conversion should be made where possible, of compound fractures into simple fractures, following a *débridement*, the cases usually calling for delayed primary suture. Earlier passive motion and massage of contiguous joints in all fractures is advisable. General adoption of the Thomas outfit for the transportation of cases with fractures of the extremities is urged.

(7) The radiologist should indicate more careful localization of foreign bodies with indelible marks upon the skin before open operations for their removal.

(8) Routine closure of wounds of joints after thorough mechanical cleansing should be practised.

(9) Early incisions are called for in septic joints in conjunction with Dakin irrigations and passive motion.

(10) Ether and chloroform should be displaced by the safer and better methods of anociassociation or local anesthesia. Cushing advocated local anesthesia for all craniotomies; it is advocated by others for all operations on the chest, and it certainly is called for in almost all minor operations.

(11) The employment of trained attendants for late treatment of cases with functional results below normal is recommended and the establishment of schools for the re-education of the industrial cripple.

(12) The war has taught many lessons and it would seem that their greatest field for usefulness is in industrial surgery, in which field they apply not only to the specialist but to every general practitioner who is occasionally called upon to treat such cases.

WELFARE WORK IN A JAPANESE ELECTRIC PLANT

By GEORGE M. PRICE, Director, Joint Board of Sanitary Control, New York City

THE presence of representatives of Japanese employers' and workers' organizations at the recent International Industrial Conference at Washington has disclosed some very interesting facts as to industrial conditions in Japan. During the last four or five years Japan has made giant strides in industrial progress with a large increase of industrial establishments and a correspondingly large transfer of agricultural workers to industrial fields.

Need for Welfare Work

Among the better class of employers there seems to be an honest desire to improve factory conditions which seem to have been deplorable until now. Japan, like other countries, has not escaped industrial unrest. In a private letter, received last fall, my correspondent writes as follows: "We have here in Japan many strikes, the result of unfair treatment by employers. The newspapers are full of discussions on industrial conditions and on the need for better treatment of factory workers. For four days, July 31 to August 3, 1919, the important newspapers in Tokyo were discontinued owing to the strike of the printing workers."

It is interesting to note that there is a demand on the part of many enlightened employers for better instruction on factory sanitation. This is evidenced by the translation of my book "The Modern Factory" into Japanese. Mr. Seishin Otsuka, who is the head of the Welfare Work in the Tokyo Electric Company, Ltd., writes me that my book was "largely responsible for the improvement of factory sanitation in a number of plants." Mr. Otsuka has sent me a number of photographs of sanitary and welfare features of the Tokyo Electric Company works, the reproduction of which would probably be of interest to the readers of Modern Medicine. These photographs show the wearing of respirators by the workers, some advanced ventilating apparatus, medical examination of workers, and other features of modern care of workers.

Factory Acts Inadequate

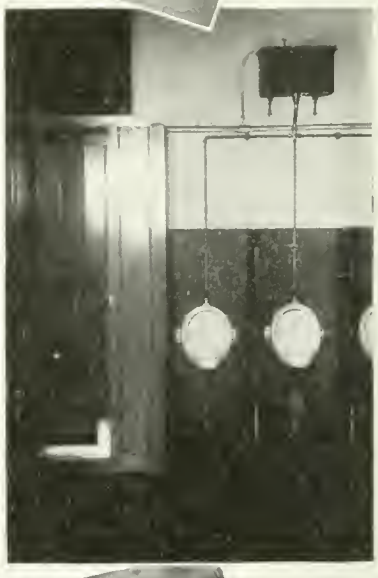
The delegation to the recent international conference included Mr. I. Kamada, president of the Keio University.

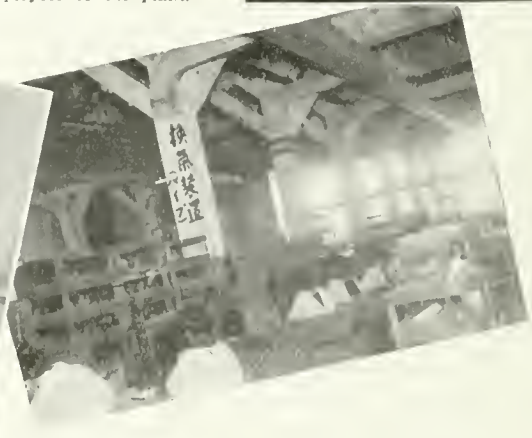
The Japanese Factory Acts are too meager and too inadequate for the protection of workers. The larger companies have introduced certain beneficial measures for the welfare of their operatives. These make provision for recreation, recuperation, and housing of their workers. There are likewise provisions for education of children, for the protection of mothers and children, and for the protection of families of employees when the head of the family is absent on military service. One company states that it gives a special holiday on the occasion of the marriage of an employee without deduction of the wages or bonus. Another company states that employees and operatives may at any time address complaints or petitions to the manager. Another company established a loan office and a domestic inquiry and

consultation office where operatives are invited to consult freely about their troubles. This company likewise appointed a committee on punishment from its own employees and operatives, which committee has to deal with the punishment for violations of the regulations of the company. Dormitories, cottages, restaurants, lunch-rooms, etc., are also provided by a number of employers.

The following is a characteristic statement by one of the companies: "In Japan, where circum-

Respirators are provided for protection against fumes or abrasive dusts. This picture shows a worker so protected. The writing in the picture describes the use of respirators by employees of the plant.





The Tokyo Electric Light Company, Ltd., requires preliminary physical examination of employees. Weight, height, heart capacity, and other matters pertaining to general physical fitness are made a matter of record. The Company provides for emergencies requiring beds, nursing, and medical care. That the space requirements are apparently not those of Occidental types may be observed in the upper, right-hand illustration. The Japanese factories have instituted up-to-date safety measures against fires. An important part of this program is the regular fire drill, which is shown in the middle, left-hand picture. All plumbing and other sanitary provisions are of the most approved type. The firemen's uniforms, shown in the lower, left-hand picture, do not bear much resemblance to those employed in other countries. This photograph shows drilled men ready for action. The Company has provided a modern system of ventilation for the benefit of its workers.

stances are different from those in the West, companies are at certain seasons obliged to have more hands than at others. The spare hands are allowed to take rests by turns and in one case received 70 per cent of their wages while off work." Some companies have established industrial schools for operatives, educational institutes, schools for girls, and memorial funds.

It would be interesting to know how far the welfare work of Japanese employers has permeated the industrial establishments in the country, and the attitude of the workers themselves towards the welfare work of the employers.

DENTAL DIVISION OF THE METROPOLITAN LIFE INSURANCE COMPANY

By T. P. HYATT, D.D.S., Director, New York

The Dental Clinic of the Metropolitan Life Insurance Company was established in July, 1915. There are seven chairs, each fully equipped. There is one dental director, one assistant director, one dentist, five dental hygienists, one radiographer, and eight women assistants. The work is confined to prophylactic treatments, x-ray examinations, first aid treatments, and careful examinations in regard to the condition of the mouth. At the time the examination is made slips (Figs. 1 and 2) are provided which show the teeth that need attention and the location of the cavity. Employees are given one of these slips, and are advised to visit their own dentists, to have the necessary work done.

Until March, 1919, the attendance on the Clinic was voluntary. The benefits obtained by those who systematically came to the dental clinic were so obvious that the following ruling of the company was made in April, 1919:

"*Dental Examination Now a Requirement*: The services rendered by the Dental Division since its establishment in 1915 have been so curative of impaired health conditions and so permanently helpful to the employees who have taken advantage of the opportunities offered, that henceforth every Home Office employee will be required to undergo examination and cleansing of the teeth in the Home Office Dental Division twice a year. If the service of the family dentist is desired rather than that of the Home Office dentists, such examinations and cleansings by him will be accepted, but they must be procured without expense to the company, and the employee must furnish a satisfactory certificate from him that the required work has been done."

That regular and frequent visits to the dentist for prophylactic treatments, followed by later home care of the teeth is beneficial is shown by figures secured in the clinic.

The employees using the service of the Dental Division have for the purposes of this study been divided into four classes: (1) those who have attended the clinic continuously since 1915; (2) those who have attended continuously since 1916; (3) those who have attended continuously since 1917; and (4) those who have attended continuously since 1918. By our system of recording, the condition of the mouth with respect to cleanliness is graded as "Yes," "No," or "Fair." As this grading is done by six different persons, the uniformity in actual practice was tested by having a single patient examined successively by the six different operators. The fact that each of them, without knowing the object of the test, placed this patient in the same classification would indicate that they held the same ideas as to standards of mouth cleanliness.

clean mouths and the lowest of those considered as not clean; Class 4, the shortest time under treatment, has the highest number of unclean mouths; and Classes 2 and 3 show a gradual tendency to grade higher in the percentage of hygienic mouths.

A further study of Class 4 shows that of those who made their first visit to the dental clinic in 1918, 10 per cent are credited with clean mouths, 57 per cent with unclean mouths, and 33 per cent were "fair"; while of those who made their second visit in 1918, 14 per cent were in the highest class, 53 per cent were "fair"; and only 33 per cent are charged with unclean mouths, a gain directly attributable to the educational and corrective work of the dental clinic of 4 per cent in the "clean" class, 20 per cent in the "fair" class, and a reduction of 24 per cent in those rated as "unclean."

FIRST RECORD TO BE MADE IN BLACK INK SECOND IN RED INK THIRD IN GREEN INK FOURTH IN VIOLET INK
Form M.D.61
Statistical data are compiled on forms such as this, the reverse side affording information which may lead to conclusions as to the relationship of mouth conditions to general systemic disease.

Conditions of Mouth Cleanliness

Other interesting figures secured through our statistical examination show that the occlusal surfaces of the teeth are the more prone to decay. After the twenty-fifth year, the number of cavities appearing upon these surfaces gradually diminish. On the other hand, cavities appearing upon the interproximal surfaces of the teeth increase year by year as the patient grows older. This brings out the importance of using floss silk in between the teeth after the twenty-fifth year, and that up until this time it is not essential for the patient to use floss silk.

Every patient is given a copy of a pamphlet upon "Home Care of the Mouth," and also a bottle of lime water with instructions as to its use. It is interesting to find that after one year's use of the lime water, and the more careful attention given at home, that of 850 persons only 53 failed to show improvement of the mouth condition. A large number of those that were recorded as not having clean mouths were found to have improved to either fairly clean or perfectly clean, and the same was found to hold true in regard to those recorded as fairly clean. They were changed to perfectly clean.

It is much easier to bring patients with unclean mouths into the class of fairly clean mouths than it is to bring them from the fairly clean to the perfectly clean class.

In view of the fact that it is impossible to detect infection surrounding root ends, we have always insisted upon making radiograph pictures of every known pulpless tooth

and of all teeth having crowns or bridges of any kind. A statistical examination was made by the statistical department of the company of 2,000 cases, divided into two classes, 1,000 in each, one class being persons who as far as examination showed, did not have any pulpless teeth. The other class were known to have pulpless teeth, of which radiograph examinations had been made. While this number is not sufficiently large to justify dogmatic conclusions as to the ratio of increase of systemic ailments among those suffering from dental infection, it is

Inasmuch as the 1,000 who were not suspected of having pulpless teeth had not been radiographed, it was deemed advisable to take out, haphazard, one hundred of these charts, and make a more careful and detailed dental examination. Forty per cent were found either to have impacted teeth that were unsuspected, or teeth, the pulps of which had died under fillings and, though radiographically there were clear indications of infection at the root end, the teeth were not sufficiently changed in color in the crowned portion to attract serious attention in making the

sufficiently high to warrant the belief that great attention must be given to dental lesion, when known to be present in those patients suffering from systemic disturbance. It was found, among those patients having pulpless teeth, that certain ailments were increased by a very large percentage. Neuralgia and neuritis were increased 118 per cent; headache was increased 68 per cent; nervous troubles, 164 per cent; colds and nasal fossa troubles were increased 19 per cent; furuncles increased 87 per cent; abscesses and skin troubles, 73 per cent.

ordinary examination of the mouth. Should this same ratio prove true for the balance of the 900 cases in this class, it would mean that the percentage of systemic disturbances among patients with pulpless teeth will not be diminished, but will be increased. The record chart (Figs. 3 and 4) are of value in statistical work, as it combines dental and medical conditions. If a chart of this kind were adopted by all industrial dental clinics, and all conditions recorded, the results to be compiled at one central office, much valuable and interesting data would be se-

cured. Data that will be sufficiently trustworthy can only be drawn from many thousands of cases. It is impossible to secure sufficient data from only one dental clinic; such statistics will need the cooperation of all the industrial dental clinics throughout the country.

No hospital is properly equipped to take care of patients, particularly those who are helpless and confined to their beds, that does not have a dentist in attendance and a complete staff of dental hygienists to give daily care to mouth hygiene.

A continuous record of examinations made is kept which shows all essential matters relating to the department from which the patient comes, the time consumed, and the man who rendered the service.

There is not the slightest doubt that insurance companies are taking unnecessary risks in the issue of large policies, when a careful dental and radiographic examination is not made of the applicant. The same applies to all hospitals, and it is a most remarkable fact that less than 2 per cent of the hospitals of our country make any sort of provision for dental examination, dental radiographic examination, or dental treatment.

While it is true that hospital dental examinations and dental treatments might not prove as valuable from a statistical point of view as those secured in industrial dental clinics, the care of hospital patients would probably be conducted with greater prospects of the recovery of health of those so treated. Many virulent diseases not caused by these dental infections and pulpless teeth, are treated successfully only after the dental infections are removed.

It must not be inferred from this that we ignore the fact that other focal infections play their part; we refer in this category to those cases where the presence of other focal infections has been carefully looked for and eradicated.

The question whether it is advisable or inadvisable to retain teeth, the pulps of which have to be removed, is a question that can only be scientifically answered through the cooperative efforts of the medical and the dental professions in securing a large array of figures from which accurate percentages may be found.

As nutrition is the most important problem in the care of convalescent patients, it is astonishing to find that hardly a hospital in the country gives any attention to the scientific and proper care of the mouth. The difference between a clean mouth and a dirty one, from a bacteriological viewpoint, is so great that it may well be that the question of success depends largely upon mouth condition. "The difference by weight and count in the number of bacteria per milligram of tooth scrapings in dirty mouths to that of reasonably clean mouths has been shown by Kligler and Gies to range from eight hundred millions in the dirty mouth to five to eight millions in the clean mouth."

Much attention is given to the training of nurses in the preparation of food for patients, but of what value is such food when prepared in unclean, dirty, and germ laden pots, pans, or dishes? It would be hard, however, to think of any cooking utensil as unclean and as harmful to the health of the patient as is an unclean and uncared for mouth, yet, the vast majority of patients in hospitals have unclean and uncared for mouths.

None but those specially trained to do this work can properly understand how to care for the mouth, and the day can not be far distant when those in charge of hospitals and sanatoriums will appreciate the necessity and importance of this work.

CARDIAC CLASSES FOR SCHOOL CHILDREN

Special classes have been conducted for the past two years by the Educational Alliance of New York for the benefit of children suffering from cardiac conditions, the work having been supplemented by a social service department, with results so gratifying that an appeal has been made to the Board of Education to provide such classes for all who are in need of them.

BREATHING ROCK DUST

The United States Public Health Service recently issued the following news item relating to the breathing of rock dust:

Over 200,000,000 tiny particles of dust, as sharp as ground glass, are breathed into the lungs and air passages with every cubic foot of air in some of the factories in the United States, according to a survey made by the Public Health Service.

Such dusts breathed into the lungs are never expelled. Photomicrographs show the tiny particles to be exceedingly sharp and jagged, and chemical tests prove them to be practically insoluble. Work under such conditions invites respiratory diseases and makes a real health hazard. Similar investigations in chemical factories showed that laborers were frequently exposed to poisonous fumes and gases.

The investigation was made at Niagara Falls because plants were engaged in the manufacture of abrasives, chemicals, gases, electrodes, carbons, metals, and alloys. In all of these factories the laborers were found to be exposed to dangers which would eventually incapacitate them for further work. Fortunately, over 60 per cent of the labor in these plants seeks new employment monthly and the result of exposure to such dangers is not evident, as it would be if the workers remained at the same work for longer periods.

As a result of the survey, industrial hygiene engineers devised means of removing the dust from the air and minimizing hazards from fumes and poisonous gases. In spite of the fact that the installation of such devices was expensive, factory managements immediately put them into use.

NEGLECTED DEFENSES AGAINST DISEASE

In dealing with the great group of communicable diseases which are transmitted by direct contact between man and man we have two main lines of defense,—isolation combined with disinfection of discharges, and the stimulation of artificial immunity by the use of sera and vaccines. No one would, of course, desire to minimize the importance of the former line of procedure; yet as a matter of actual experience such application as has been made of the knowledge we possess in regard to isolation has yielded results of relatively slight importance in comparison with the achievements of general sanitation and of serology. Diseases which have been demonstrably controlled on a large scale are those which, like malaria and typhoid fever, are due to environmental conditions outside the human body or those, like smallpox and typhoid fever again, controllable by specific vaccine therapy. Of the contact-borne diseases which are dealt with by isolation alone, scarlet fever is the only one which shows a marked decline, and the coincidence in this case may well be an accidental one.

In view of these facts, it might be supposed that when the discovery of a specific serum does make it possible to secure definite and tangible results in dealing with a member of this baffling group of disorders the discovery would be received with eagerness and applied with immediate effect. The breaking down of the barriers of human inertia is, however, often as slow a process as that of scientific research; and only organized and aggressive leadership gradually succeeds in bridging the gap between theory and practice.

Thus it happens that a quarter of a century after the discovery of diphtheria antitoxin the fruits of that discovery are not fully garnered. We possess a more complete knowledge of diphtheria and a more complete power over diphtheria than in the case of any other communicable disease. We can detect the incipient case and the carrier. We can measure natural immunity by the Shick test. We can produce passive immunity by the use of antitoxin and active immunity by the use of toxin-antitoxin mixtures. Every weapon which could be needed to fight this enemy is in our hands, yet diphtheria continues to occupy third place among the communicable diseases and kills eleven or twelve thousand persons in the registration area each year.

The recognition of the importance of medical attention in every case of sore throat in a child and the prompt use of antitoxin by physicians in every case that simulates diphtheria would do much to reduce this factor in the death rate to small proportions. The application of the Schick test to all children entering school, and the immunization of all positive reactors with toxin-antitoxin would accomplish even more. The routine treatment of infants of six months with the toxin-antitoxin mixture would stamp out the disease completely. Is it not time that the health officers of the country should set themselves vigorously and effectively at the task of persuading the medical profession and the public to banish diphtheria, with typhus and yellow fever, to the limbo of historic pestilences.

In pneumonia we are dealing with an enemy far more deadly even than diphtheria, an enemy which kills over 100,000 persons in the registration area in normal years. Here our armamentarium is far less complete than in the case of diphtheria, yet for the pneumonia caused by the Type I pneumococcus, which in ordinary years probably causes about one-fifth of the deaths due to pneumonia in all forms, we have a serum of proved therapeutic value. The least we can do, as health officials or as physicians, is to see that in all cases of lobar pneumonia the type of the infecting organism is determined and serum used for the treatment of every case in which the Type I pneumococcus is the primary invader.

There is no more fruitful line of effort for the

health officer than the stimulation by every means in his power of the use of serum therapy as a weapon against diphtheria and pneumonia; there is no graver responsibility resting upon the practising physician than the duty of making the fullest use of the recent contribution which bacteriology has made to the machinery for combating two of the most deadly communicable diseases which continue to menace mankind.

EDITOR.

A CRITICAL SURVEY OF PUBLIC HEALTH TOPICS

By JULES SCHEVITZ, General Secretary, Oklahoma Tuberculosis Association, Oklahoma City

I. What Are the Duties of the Private Health Agency?
II. School Medical Supervision in Framingham.
III. Poisoning by Wood Alcohol.

I. WHAT ARE THE DUTIES OF THE PRIVATE HEALTH AGENCY?

CONSIDERATION of the functions of public and private health agencies—that is, the official health department on one hand and the voluntary health organization on the other—is bound to bring forth many differences of opinion. It being admitted that to the public health officials is intrusted the responsibility of protecting the community from disease, the question is then asked what part has the private health agency in such a program?

There seems to be a disposition on the part of certain workers to assign to each agency a definite share of the program. For example, Dr. H. W. Hill, who has had experience as an official health representative as well as the head of a voluntary health agency, intimates that the official health department should concern itself more with carrying on its police functions and leave many phases of the health educational program to the private organization.

To quote Dr. Hill:[1]

> The whole time health officer who does his own proper duty against disease will have his hands full and will find that non-compulsory fields have waiting to occupy them staunch moral supporters with time and money plentiful, who will cooperate with him in his work all the better for working themselves on these voluntary measures.

The validity of this action was quickly challenged and the following objections to the plan submitted by Dr. Hill have been offered:[2]

(1) Divided responsibility for public health will result in lowering standards of official health administration.

(2) Compulsory health work is dependent for its efficiency on the educational preparation of the public for compulsion, and health education, to be most effective, must be brought to the public by the one who has official authority, namely, the health officer.

(3) If official health departments are concerned only with police regulation of infectious diseases, there will be little in official health service to attract well trained, whole-time executives.

(4) The removal of educational health work from the control of official health departments will handicap such departments in securing adequate appropriations, even for the very essential work necessary.

A recent editorial in the *American Journal of Public Health*,[3] entitled "What Are the Duties of the Public Health Officer?" discusses the relation between the public and private health fields from the wrong angle. As the title of the article indicates, there seems to be some doubt as to the functions of the public health official. It should be distinctly understood that the public health officer, as the official guardian of the public health, should employ every known method for the control of disease and the promotion of health. The form of activity employed by the health department must not be limited or circumscribed in any manner. There is no need for defense of the activities or functions of the public health officer. If any question is raised, it should be, "What Are the Duties of the Private Health Agency?"

Has the private or voluntary health organization any justification for its existence? Certainly it does not operate to hinder or limit the progress of the official department. Let us see where it can do the most good. Private health agencies have played an important rôle in the development of the public health campaign and will continue to do so in the future by conducting health activities which may at first be considered experimental.

The demonstration to the proper public officials of the proved efficacy of certain novel health measures is acknowledged generally to be a valu-

1. Hill, H. W., M. D.: What is the Matter with Public Health Today? Am. Jour. Public Health, November, 1919, 827.
2. McCombs, Carl E., M. D.: Public Health Departments and Private Health Agencies, Am. Jour. Public Health, December, 1919, 951.
3. What are the Duties of the Public Health Officer? Editorial, Am. Jour. Public Health, December, 1919, 966.

able contribution by the voluntary agency to the health movement. The employment of public health nurses, the operation of health dispensaries, and the development of the public health educational program, are a few examples of advances in the modern public health movement in which the voluntary agency occupied a leading part.

As soon as the official health department is prepared to assume these new activities, they should be turned over to it by the private organization. In fact, one of the most important functions of such an agency is to aid in the growth and expansion of the program of the official department. There are many instances where public health officials will admit that certain activities can be handled more efficiently by the private agency, because of the presence of politics in the health departments or for other reasons; but in these cases the private agency should strive to remove the obstacle in the way of efficient governmental activity.

There will probably always be a legitimate and useful place for the volunteer health organization. To even the most highly organized health department the efforts of the private agency may be found extremely helpful.

II—SCHOOL MEDICAL SUPERVISION IN FRAMINGHAM

THE Framingham, Mass., Health Demonstration, conducted under the auspices of the National Tuberculosis Association and financed by the Metropolitan Insurance Company, has been more than an attempt at the discovery and control of cases of tuberculosis in that city. It has resulted in the building up of a health machinery in Framingham which places that city in a class by itself.

Framingham is attempting to solve its school health problem in its broadest sense, and undoubtedly has the best school health machinery in the state. The staff consists of a full-time school physician, nurse, dental hygienist, teacher of posture training, physical training teacher, and a part-time dentist for a unit of approximately 2,500 grade school children. An account of the results of the physical survey of the school children appears in a recent issue of the Boston Medical and Surgical Journal.[1] The following figures selected from the complete tables give a good cross section of the condition of child life in Framingham. Future surveys will show how effective this school health machinery has been in dealing with existing conditions.

1. Bost. Med. and Surg. Jour., 1919, clxxxi, No. 14, p. 427.

PREVALENCE OF CERTAIN PHYSICAL DEFECTS

Total number of children examined.....2,449

	Percentage of Total		Percentage of Total
Nutrition Excellent	6.8	Defective Vision	6.5
Nutrition Good	43.0	Defective Hearing	1.1
Nutrition Fair	41.9	Discharging Ears	1.0
Nutrition Poor	8.2	Skin Diseases	3.5
Defective Teeth	60.0	Postural Defects	12.0
Enlarged Tonsils	46.0	Nasal Obstruction	12.0
Anemic Condition	16.1	Pulmonary Tuberculosis	0.45
Enlarged Glands	45.2		

The children were stripped to the waist and a thorough examination of the lungs made. Eleven cases of pulmonary tuberculosis were discovered; 64 others will be kept under observation.

III—POISONING BY WOOD ALCOHOL

THE enemies of prohibition have probably viewed with some satisfaction the wave of wood alcohol poisoning which spread over the country during the Christmas holidays. Considerable publicity was given everywhere to all deaths from this cause and prompt and energetic action on the part of health and prohibition enforcement authorities was in evidence.

The use of methyl alcohol for either internal or external human use constitutes a violation of the health regulations of most local and state health departments. With the poisonings resulting from the substitution of methyl for ethyl alcohol in beverages, more stringent regulations were passed, in some cases governing the methods of sale of the wood alcohol. Because of the very apparent and easily recognized effects of this poison and the watchfulness on the part of the authorities, it is not expected that the use of wood alcohol for drinking purposes will be at all widespread.

A warning issued by the New York City Health Department regarding the adulteration of external preparations with wood alcohol, says:[1]

> Since refined wood alcohol tastes like ethyl alcohol, and, in the past, has been used in the preparation of essence of peppermint, Jamaica ginger, lemon extract, cologne, Florida water, witch hazel, and liniments, it is important to remember that poisoning may result from such adulteration. Such use . . . subjects anyone attempting it to criminal prosecution.

The symptoms of wood alcohol poisoning are similar to those from ethyl alcohol, only they come on more slowly and are more prolonged.

Grip Epidemic in Japan

Reports are current to the effect that an epidemic of influenza similar to that of last year has broken out in Japan. Japanese papers report that governmental measures have been taken to control the disease.

1. Weekly Bulletin, Health Department of the City of New York, January 10, 1920.

DETECTION OF TYPHOID CARRIERS

By F. M. MEADER, M.D., Director, Division Communicable Diseases, New York State Department of Health, Albany, N. Y.

TYPHOID fever is so well under control in many of the states that the extensive outbreaks due to water-borne infection or to infected milk are no longer recognized. The cases are now, aside from secondary cases in the same family, only few, and occur sporadically in widely different sections of the county. The exact source of infection is often very difficult to determine. This has brought about new methods in the effort to reduce typhoid fever to a still lower case incidence.

THE MENACE OF TYPHOID

Typhoid fever is now so well under control that health measures directed against it are more often concerned with sporadic cases than with typhoid in epidemic form.

The cases that occur are usually either secondary cases in the same family, or sporadic cases in widely different sections.

To eradicate the disease, the health officer must trace the connection between these sporadic cases. By far the most difficult source of infection to trace and the most baffling to control is the typhoid carrier, and methods for the cure of typhoid carriers are among the most needy research problems.

Investigation by Counties

The efforts now to control this disease should be placed upon a larger unit of area than has hitherto been done. We have been accustomed to investigate the cases of typhoid fever in single municipalities. It now seems best to investigate typhoid fever by counties, selecting first those counties in which, during the year, the largest number of cases have appeared. When this is done, it is possible to trace the connection between sporadic cases occurring in the various municipalities. The person who investigates these cases must be particularly well trained in laboratory procedures, so that he can apply promptly methods which will aid him in deciding the usefulness of the various clues which his detective instinct presents to him. The epidemiologist is a detective whose duty it is to discover the hidden lair and paths leading thereto, for the infectious agents of communicable disease.

The epidemiologist, in his search for sources of infection of typhoid fever, realizes that the cases have their source of infection in either a case or a typhoid carrier. It therefore becomes necessary for him to find out the possible cases or carriers with whom the patient has come in contact just before the incubation period of the case in question. The first information of value to determine is the date of onset. He then knows that his patient was infected from seven to twenty-one days before the onset .

In his search it is often found that unreported cases have existed in mild form in whom the presence of the disease was not suspected. It is then essential to determine whether or not the party did have typhoid fever, and for that purpose it becomes useful to take a sample of blood for a Widal test. Often these missed cases prove to be the connecting link between his patient and the case or carrier for whom he is searching, so that the epidemiologist must be familiar with immunity reactions to help him in directing his efforts.

Laboratory Close to Case

The epidemiologist must also be able to discover the typhoid organism by means of bacteriological examination. If he realizes how difficult it may be in certain instances to isolate the organism, he will be more careful in obtaining his specimens and he will insist upon its prompt examination. He will sometimes desire to make the bacteriological examinations at the place rather than transfer material any distance. In recent years the use of containers which hold a certain amount of glycerin has proved of considerable assistance, so that these specimens of material can be transmitted longer distances to the laboratory than has hitherto been possible.

Often the question of an infected water supply must be ruled out before proceeding in the detection of other sources of infection. The simple chemical methods of examining water for an unusual amount of chlorin may be of great assistance, so that the epidemiologist must be equipped with considerable knowledge of laboratory technic. Immunity reactions, bacteriological methods, and chemical procedures should be at his disposal.

There is another group of phenomena which will be of the greatest assistance to the epidemiologist in his search for sources of infection: namely, the characteristics of outbreaks of ty-

phoid fever when the infectious agent is conveyed by various means, for example,—water-borne, milk-borne, fly-borne, communicated by contact. Each course of transmitting infection has a history of onset to the outbreak which is peculiar to itself. Milk-borne outbreaks will appear suddenly, followed by a rapid decline. The usual incidence will be among women and children more than men, and the cases will appear in unusual number among the customers of certain dairies. Water-borne outbreaks will occur among persons residing in an area supplied by a particular water. The usual seasonal prevalence is spring or late winter. An outbreak will follow a change in water supply. A large percentage of the cases will be among adults, and an examination of the water reveals evidences of pollution.

When well waters are infected, there is suddenly a large number of persons who use that particular water who become ill with the disease, whereas there is comparative freedom from typhoid fever among persons who do not use water from that particular well. Outbreaks which are spread by contact usually occur, few in number, at irregular intervals and over a period of considerable time. Sanitary conditions may be bad, but this is not always apparent to the general public.

Conditions to Be Noted

In finding the sources of infection, as stated above, the first bit of information which the epidemiologist will obtain is the approximate date of the onset of the disease. He will then study carefully the period of seven to twenty-one days prior to the date of onset. His inquiry will be limited to this period. He will inquire into associations with cases, unusual visits or associations. Picnics, parties, and unusual food consumed during this period, will be carefully inquired into. The association of the case with persons who had typhoid fever the previous year will be investigated. If this work is carefully done with these obscure cases, it will in a large proportion of the cases be possible to show an association with a person who complains of symptoms of gall stones, jaundice, or recently infected with typhoid fever.

It is of the greatest importance, when possible, to obtain all information from the patient himself rather than from friends or relatives; however, if the patient is very ill, he should not be bothered with questioning upon this subject. If the information given by friends is not sufficiently definite to locate the source of infection, the matter of questioning the patient should be deferred until he is able to give the desired information.

When a person is suspected of being a typhoid carrier, it is necessary to obtain from that person a specimen of feces and urine for bacteriological examination. In obtaining the specimen it is usually wise to obtain specimens from several members of the household, and not indicate the suspicious person particularly. Further, it is often of the greatest service to enlist the physician's cooperation in the matter and ask him to obtain the specimens. The reports which come from the laboratory will be better received by the patient if the specimens are collected by the family physician than if obtained by persons with whom they are unacquainted.

When there are received from the laboratory reports which indicate that a certain person is a carrier, it then becomes necessary to take up the question of what to advise the person who is a typhoid carrier.

At the present time we have about fifty-six typhoid carriers under observation in the state of New York, exclusive of New York City. A report blank is sent quarterly to the health officers of the municipalities in which these cases are located, copy of which is presented herewith.

(1) The patient is notified that he or she is a typhoid carrier. This is probably one of the most effective measures to take, as intelligent persons who realize that they are carriers are able to take care of themselves and their excreta in a way that they will not become a menace to other people of the community.

(2) Typhoid carriers are not permitted to have anything to do with the handling of milk or food supplies for public consumption. Where this restriction is such a hardship that the person is deprived of a livelihood, the State Department of Health, through the county poor officer, gives an allowance monthly to supplement the earnings of the patient who cannot engage in work which will endanger food supply. Housewives are permitted to continue the preparation of foods for their families, but not for public consumption. The remaining members of the families are expected to be immunized with typhoid vaccine.

(3) Sanitary conditions of the place are so arranged that access of flies to excreta is impossible, and drainage into water supplies is prevented.

(4) The patient is advised to have a disinfectant for the hands always easily available, and that thorough cleansing and disinfection of the hands be done several times daily.

(5) It is not deemed necessary that the information that a person is a carrier should be given to more than the health officer, the physician, the patient, and some other member of the family.

The withholding of this information from the public by the health officer is of great assistance in enforcing regulations should the patient be inclined to be careless, as all carriers, of course, will do almost anything to keep this knowledge from their friends.

(6) Often the Department sends a letter to the patient explaining the condition, outlining the procedure mentioned, and asking for their cooperation. This then is followed by a visit from the health officer. We present a copy of letter usually sent to these carriers which indicates the tone believed to be most effective.

The matter of treating these carriers is one which has received some attention by this department. Three or four carriers have apparently been cured by the use of typhoid vaccines, but so many others have not been cured by the use of vaccines that its value as a general measure is problematic. The removal of the gall bladder is probably the best method of curing typhoid carriers. It will not always cure the carrier, but in many instances apparently it does. In our opinion, the methods for the cure of typhoid carriers are among the most needy of research problems. As the number of carriers is certainly very large, the establishment of a recognized method for their cure would be of great benefit.

COPY December 24, 1919.

Dear Mrs. C.:

This Department has been engaged for some time in the work of finding the sources of cases of typhoid fever in various parts of the state. Among the frequent sources of infection are found to be persons who have had typhoid fever years ago but who are still harboring the organism in their bowel excreta. In these cases the usual source of infection is the gall bladder, and organisms of typhoid fever multiply here and discharge out into the intestinal tract. These people are immune to the disease, hence do not suffer from it now, but they are a great source of danger to other people who are not immune to typhoid fever.

The examination of the specimen of excreta which you supplied this Department a little while ago revealed the presence of these organisms, indicating clearly that, unfortunately, you are what we call a typhoid carrier.

We have a great many typhoid carriers in the state and are requiring of them simple precautions in the matter of disposal of their excreta and a careful toilet of their hands. A disinfecting solution should always be available for disinfecting the hands several times daily. It is also required that these people have nothing to do with the handling of milk, milk products, or the utensils used at a dairy, or with food that is to be used raw for public consumption. These people are further prohibited from preparing food for public consumption. They are, however, permitted to prepare food for their families; but the members of their families should be immunized, in order to prevent them from becoming infected. Your physician can advise you regarding this matter.

The sanitary conditions of the toilet must be such that discharges from the bowels can be disposed of without flies having access to same and where it will not drain into water supplies. Enclosed is the Department's circular of special rules and regulations to be observed, which your health officer will explain to you in detail.

The question of curing the condition is a very difficult one. Recently five out of seven typhoid carriers were cured in one of the army hospitals by having the gall bladder removed Up to the present time this method is the most satisfactory known. If you would care to take this matter up with your physician, I shall be glad to supply him with any information which we have.

With our other carriers it is found that the most important precaution is to let the patient know that she is a typhoid carrier. She is then able to take proper precautions to prevent the infection spreading.

This Department hopes for your cooperation in this matter and expects that we shall have no further trouble in regard to the spread of this disease.

Very truly yours,
Director, Division of Communicable Diseases.

Hermann M. Biggs, Commissioner, State Department of Health, Albany, N. Y.

Division of Communicable Diseases

QUARTERLY REPORT BLANK FOR TYPHOID CARRIERS

To the Commissioner:

Dear Sir: The following report is offered for the quarter ending March 31, June 30, Sept. 30, Dec. 31, 19.....

(Cross out words that do not apply)

Town .....
Village ..... County.....Primary Dist. No.....
City .....
Patient..... Street Address.....
Attending Physician..... Address.....
During the quarter M..... has not engaged in the handling of foods. The following kinds of work have been done .....
.....
.....
M.....has in his possession.....lbs. chloride of lime and.....disinfectant for hands. Approximately .....lbs. of chlorid of lime and.....disinfectant have been used during the quarter. Excreta are deposited in a flush closet, privy, trench; a spring, well is / is not located near the cesspool, privy, trench; flies do / do not have access to excreta. The patient uses an individual towel and frequently disinfects his hands. The patient's / her excreta were examined as follows:
Date..... Result..... By Whom.....
.....
.....

The following trips out of this municipality have been taken:

To..... Date..... Date Returned.....
To..... Date..... Date Returned.....
How many people residing in the home? .....
How many have been immunized? .....

Total cases of typhoid fever occurred in this municipality during the quarter..... The following number of cases have received their infection from this typhoid carrier.....

Signed .....H. O.
Address .....

Note: In certain instances it may be advisable for the health officers to ask the attending physician to obtain the above information.

REDUCTION OF INFANT MORTALITY

By D. M. LEWIS, M.D., State Director, International Health Board, Charleston, W. Va.

In a previous article[1] I have shown the results obtainable from the application of the study of the causes of infant mortality as gained from mortality statistics. Reasons were given as to why part of the 31 per cent always listed as due to congenital malformations and debility, and the 21 per cent listed as due to causes not susceptible of analysis, might not as well be dependent upon the same factor, namely, the acute infections. If so, curve rates for an ordinary year as contrasted with an extraordinary one for the acute infections should show relations with that for congenital malformations and debility. The relationship not only in general but in many minor particulars stands out so clearly in the records which I keep of other cities in contrast with work done here, as to be unhesitantly placed on record as proof of our premise.

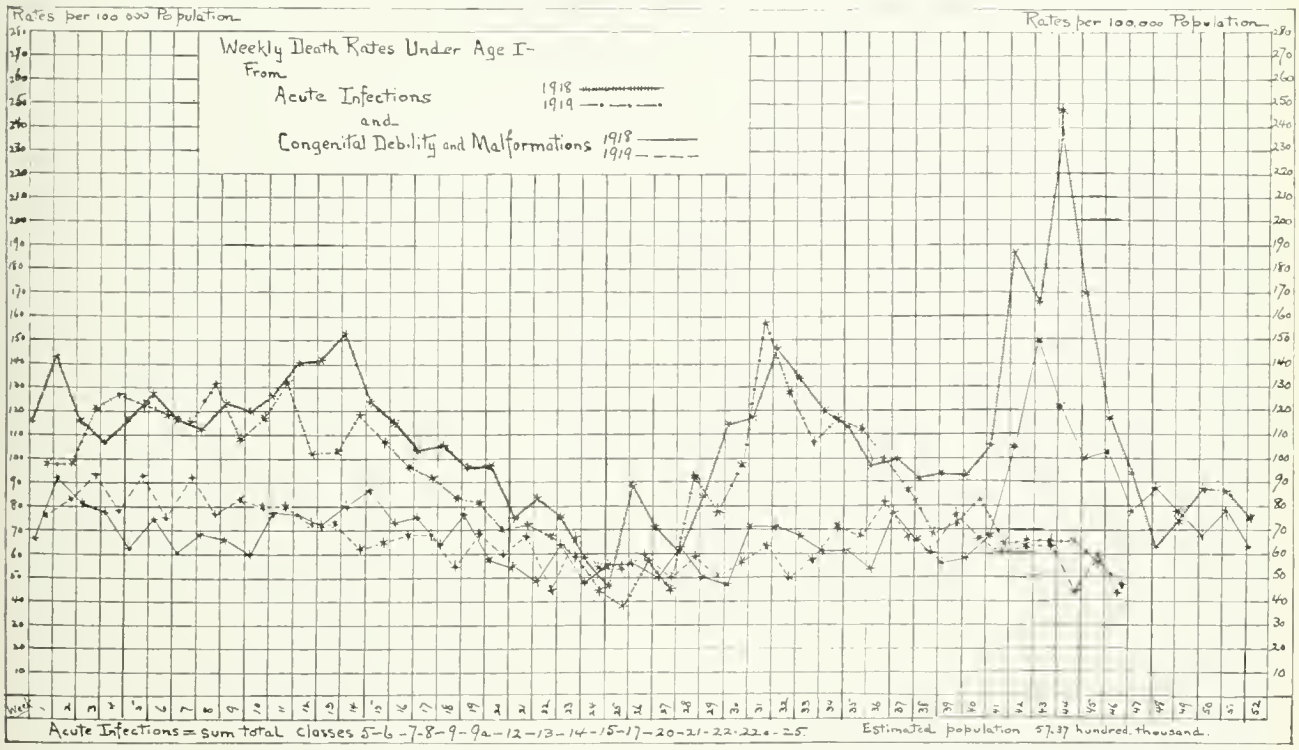
The Method of Comparison

The illustrated curves are from the *Weekly Bulletin* records of New York City converted into annual rates for 100,000 population. I have used the same population for both years in that comparison should be made only between the curves of each year, and for the fact that while the estimated population in 1918 was 57.37 per hundred thousand, the Bureau of the Census estimates the population for July 1, 1919, as 52.16 per hundred thousand, while New York claims 60.00 per hundred thousand. After the present census is taken, correction made for one of the two years will make comparative readings of both curves for both years possible should one wish such relationship. In that under "all other causes" as a cause of death there is weekly a further amount of congenital causes in excess of those there listed as from infections, there should not be looked for an absolutely accurate rate for either of the two curves.

Agreement of Curves

The general agreement of the two curves during the winter of 1918 is very striking compared to the minimal ones of the end of the first half year. No less so is that of the less prolonged summer rises. Most striking is the agreement of the October, 1918 (weeks 40-44) curves. The absence of a maximum rise in the congenital curve for the forty-fifth week should be regarded as a further strong point in the argument. Medical diagnosis was predominantly influenza. Specific-

1. Lewis, D. M.: Infant Mortality, Theory and Results, Bost. Med. & Surg. Jour., Oct. 17, 1918.



Curves indicating weekly death rates in 1918 and 1919 of infants under one year of age from acute infections and congenital debility and malformations. The curves are based on the *Weekly Bulletin* records of New York City converted into annual rates for 100,000 population.

ally, one may read the apparent first "flu" wave of the last two weeks in March and first week in April, 1918 (weeks 12-13-14), the increases of the first two months of 1919, and the lesser rates of the summer of 1919. Worthy of further interpretation is the lag of the congenital curves of summer infection compared to those of winter. As not germane to the discussion, we merely acll attention to the fact.

The Need for Close Analysis

Inasmuch as the sum of the deaths and their total in terms of specific groups are being used as the results of prenatal clinics and other welfare activities, Nature's hurricane of 1918 which spoiled the mortality records at all ages as well as those for infant mortality for the year as compared to the continuing previous reductions, make essential renewed studies from the point of view of mortality statistics rather than glossing over the year as an unusual one representing a mass of increased social disturbances.

Since the completion of the accompanying chart I have found in a recently published book[2] English statistics which are not only corroborative of the point last made, but are definite as well of the part that the infectious diseases play in infant mortality. That relation as influenced by prevailing "grippe" years, though unexplained, is also shown in the given statistics. When one reads into "urbanization" as the given cause for the mortality records, the lesson we should have learned from the late war,—excess of infections in rurals only when rurals meet urbans,—we shall return to a study of vital statistics and find the definitely workable basis for controlling infant mortality.[3]

Summary

Vital statistics show that there is a very definite relation between the deaths from acute infection under the age of one year and the congenital malformation and debility for the same age. The increasing emphasis given to prenatal and other infant welfare work where not corroborated by statistics should be checked up with the large amount of available statistics which show that the prevalent views are erroneous, and that efforts which ignore the acute infections as causative factors are more than a waste of money and energy; they contribute to the continued vicious circle of curative rather than preventive measures of public health.

The course to an adequate mental adaptation is sometimes stormy, but it is far less devious than the paths by which people try to escape.—Fred. Lyman Wells, M.D.

THE IMPROVEMENT OF HOUSING CONDITIONS IN GREAT BRITAIN*

By Our London Correspondent

The crux of the entire health problem of Great Britain appears to depend mainly on the question of housing accommodation. The Ministry of Health by the mouths of its Minister and his chief medical advisers had stated in the most definite manner that if the situation as regards housing is not remedied as quickly as possible, the health of the people will not only show no improvement but will go from bad to worse. As Sir George Newman, Chief Medical Adviser of the Ministry, points out in his memorandum on preventive medicine issued recently, the housing problem is twofold in its relation to disease, namely, the insufficiency and unsuitability of the house accommodation available. Insufficiency naturally leads to over-crowding. Unsuitability may be due to inadequate cubic capacity, absence of ventilation, or insanitation. It is obvious that in the train of over-crowding, ill ventilation, or insanitation follow troubles of every description, ranging from minor ailments to incapacity, disease and death. According to Newman, and the statement appears to be justified, cine in which the evidence is so general as in regard to the ill effects of bad housing upon the human organism. mendous as to daunt any but the most sanguine.

The report on the Royal Commission on the Housing of the Industrial Population of Scotland, 1917, provides perhaps the most masterly and terrible indictment of the housing conditions which prevail in certain industrial centers ever penned. Broadly speaking, there are three evils which proceed from bad housing:

(1) There is diminished personal cleanliness and physique, leading to debility, fatigue, unfitness, and reduced powers of resistance. The general deterioration in the health of the people is a worse feature of over-crowding than its promotion by infectious disease. It has the effect of reducing their stamina, and thus producing consumption and diseases arising from general debility of the system whereby life is shortened.

(2) A second result of bad housing is that the sickness rates are relatively high, particularly for infectious, contagious, and respiratory diseases. Sir Shirley Murphy showed in 1898 that in districts of London where overcrowding, that is more than two persons in one room in tenements of less than five rooms, was under 10 per cent, the death rate from pulmonary tuberculosis was 111 per 100,000 people; but where the overcrowding was more than 25 per cent, the corresponding death rate was from 209 to 259 per 100,000.

(3) The general death rates are higher and the expectation of life is lower where there is over-crowding. The evidence is overwhelming and comes from all parts of the world that the worse the people are housed the higher is the death rate. There is no need to bring forward statistics to prove this point. The statement, then, that inadequate and insanitary housing goes hand in hand with bad morals, bad health, bad physique, and a lowered standard of mentality, may be taken as proved.

There is no cause for wonder therefore that the British Ministry of Health, as the first step to improve the health of the population, should try to solve the housing problem. It is a problem at the present time most difficult almost impossible to solve successfully. The cost of building new houses and of restoring defective dwellings is so tremendous as to daunt any but the most sanguine and boldest spirits.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

OUR RURAL HEALTH PROBLEMS

MORE than 50 per cent of the population of the United States is rural. The important relation between rural hygiene and the national health is therefore self-evident. When one speaks of the remarkable accomplishments of the modern public health movement in the reduction of the death rate, the elimination of certain diseases, the promotion of the public health in general, the statement should be modified to make it clear that this hygienic advancement, gratifying as it is, has been practically limited to the larger cities in the country. Very little effort has been expended in the improvement of rural sanitation, with the result that death rates of even the most congested cities compare favorably with those of rural centers, which are considered to be healthful abodes. Studies of the Children's Bureau and the United States Public Health Service into rural health conditions have revealed some surprising findings. For example, it was found that:[1]

> Of over 50,000 typical farm homes distributed over a wide range of our rural districts, only 1.22 per cent were provided with sanitary toilets, and at some which were properly equipped, the equipment was not used by all members of the household; at 68 per cent of these homes the water supply used for drinking and cooking purposes was obviously exposed to contamination from privy contents or from promiscuous deposits of human filth, and often also pollution from stable yards and pigsties; and at only 32.88 per cent were the dwellings during the summer season effectively screened to prevent flies (having free access to nearby deposits of human and other filth) from entering dining rooms and kitchens and contaminating the foods for human consumption exposed therein. In numerous instances a pond of water of no use and which could have been drained away in an hour by one man, was found near the dwelling, providing a place for the breeding of mosquitoes which play such an important rôle in the serious annual occurrence of malaria in the household.

Examination into rural conditions in counties in Kansas and North Carolina[2] indicate high maternal death rates from causes pertaining to childbirth. Few women receive prenatal advice, and the nursing care at confinement consists largely of services of untrained relatives and neighbors. Inability to secure medical attention at childbirth is not rare and this is more true of postnatal visits. Infant mortality rates have not been very high, probably because of the almost universal breast feeding of infants.

It has been well said that[3] "the rural districts of the country are suffering from ignorance even more than from poverty." Since the education of citizens is distinctly a state function it is believed that . . . the responsibility for existent deficiencies lies at the doors of the state departments of health.

The county demonstration work in rural sanitation as conducted by the Public Health Service deserves hearty commendation and encouragement. The expenses for this work are generally shared by the county, the state board of health, and the Public Health Service. Congress should lend its fullest support to these life saving efforts. The demonstration public health nursing in rural counties in Wyoming and Louisiana sponsored by the Children's Bureau will also be watched with keen interest. The need for public health nursing is manifest; the lack of sanitary homes, overcrowding, insufficient food of the right sort, poor water supply, and unsanitary privies, complicate the situation.

No big step in social progress is possible without the active sympathy of large masses of the community, and in this respect the movement for improving the national health has the greatest support.—Brend.

TRADE UNION DISABILITY INSURANCE*

By BORIS EMMET, Ph.D., Schloss Factories, Baltimore, Md.

OPPONENTS of compulsory state social insurance point to the existing trade union sick benefit systems as effective voluntary agencies for furnishing relief to wage earners in cases of disability due to sickness. It is, therefore, of great interest to students of industrial medicine to reveal the validity of this contention.

There is need of some general provision for adequate medical care in case of sickness, and cash compensation for loss of time.

That this need is not met by trade union benefits is shown by the fact that the per capita disability expenditure in 1918 was forty-one cents, the average weekly payment in all but two funds being less than five dollars.

Trade unions do not even care for all the disability in their own ranks. Compensation that does not provide medical care and as full restoration as is possible only begs the question of adequate health protection.

Two benefits are usually provided for by proposed state social insurance schemes,—medical benefits or medical care, and cash benefits. The former is, in the majority of instances, admitted to be the more important and costly one. Inasmuch as no trade union system in existence is known to provide for medical care,[1] the value of trade union, voluntary sickness insurance is nil from the point of view of medical attention. The brief study presented herewith concerns itself, therefore, wholly with the cash benefits paid by trade unions in cases of temporary disability.

Extent of Sick Benefit Systems

No actual survey has ever been made of the extent of trade union sick benefit systems in the United States. A partial survey made in 1917 by the author of this article for the Bureau of Labor Statistics, in the manufacturing centers of New York, Philadelphia, Cleveland, Detroit, Boston, and Chicago, indicated that about one-fifth of the existing local labor organizations paid some kind of temporary disability benefits. The four great railway brotherhoods and the Amalgamated Clothing Workers of America, the only large labor organization outside the Federation, do not pay any temporary disability benefits. The extent of sick benefit systems among organized labor is, therefore, synonymous with the extent of sick benefit systems in unions affiliated with the American Federation of Labor. Of the 111 national or international organizations affiliated with the American Federation of Labor, 15, with a membership of about 250,000, have sick benefit systems. The number of trade unionists receiving temporary disability benefit is, however, much greater. In view of the fact that the sick benefits paid by national unions are small, seldom even reaching ten dollars per week, many local labor organizations affiliated with the internationals in question pay sick benefits of their own. Again, some local unions pay sick benefits because of the entire absence of a sick benefit scheme in their national organization. It is estimated that the total number of trade unionists receiving cash sick benefits from their local and national organizations is at the present time about 750,000.

The claim is constantly made that the payment of sick benefits is becoming increasingly popular among trade unions. To prove this contention the annual amounts expended on sick benefits by the American Federation of Labor are quoted. These amounts, it is said, have been steadily increasing. While it is true that the absolute amounts expended on sick benefits have been increasing, the average *per capita* of membership amount has remained fairly constant. Table I shows the annual membership amounts expended on sick benefits, and average *per capita* expenditure, by year, since 1902.

Table I shows that the membership of the American Federation of Labor has about trebled since 1902 and that the amount expended on disability benefits has also trebled. One may, therefore, conclude that the extent of prevalence of disability insurance systems among trade unions has changed but little since 1902. This conclusion is substantiated by the *per capita* of disability benefit expenditures shown in the last column of Table I. This *per capita* expenditure was forty-two cents in 1902 and forty-one cents in 1918. The average *per capita* expenditure for all seven-

*This is the first of a series of three articles by Boris Emmet, Ph.D., on existing forms of disability insurance. The succeeding articles will discuss fraternal and establishment fund disability insurance. Dr. Emmet has given intensive study for years to these forms of insurance, and the editors are happy to present his researches to the readers of Modern Medicine.

1. "Operation of Establishment and Trade-Union Disability Funds," Monthly Review of the United States Bureau of Labor Statistics, August, 1917, pp. 17-36.

teen years covered by the table was forty-five cents.

The administration of the sick benefit funds of trade unions is usually carried on by the same officers that administer the general affairs of the organizations. In national and international funds the general secretary-treasurer is, as a rule, in direct charge. The investigation of the validity of claims is generally in the hands of standing committees of the local unions. One national organization only is known to have on its staff a corps of traveling investigators who go from locality to locality for the purpose of supervising the administration of the scheme. Membership in the union as a rule, entitles one to sick benefits, provided his good standing on the books of the organization is established.

In a great majority of the union funds no physical examination is required of a member joining the union and the fund. A few of the funds have a special non-benefit membership class, which entitles members to all the protective features of the organization except that of sick benefits. To this non-beneficial group belong those who at the time of entrance are above the specified age—usually 50 years—and those afflicted with chronic diseases.

Practically all of the national and local unions provide for forfeiture of benefit if illness is caused by intemperance, debauchery, or any other immoral conduct. No actuarial examination of any of the benefit funds of the national or local trade union funds examined is known to have been made.

In the great majority of the funds maintained by the national or international labor organizations the amount of cash benefits paid per week is rather small, the average in all but two funds being less than five dollars. This amount is, of course, inadequate to afford full relief, particularly in view of the fact that none of the funds furnishes any medical or hospital care to its disabled members.

TABLE I—Disability Benefit Expenditures of all Labor Organizations Affiliated with the American Federation of Labor†

Year	Membership	Amounts paid in disability benefits	Per capita expenditure (in cents)
1902	1,024,399	437,059	42
1903	1,465,800	756,763	52
1904	1,676,200	582,874	35
1905	1,494,300	663,437	44
1906	1,454,200	712,536	49
1907	1,538,970	593,541	39
1908	1,586,885	731,955	46
1909	1,482,872	719,166	48
1910	1,562,112	818,557	52
1911	1,761,835	793,256	45
1912	1,770,145	816,336	46

Workings of Typical Benefit Funds

A report published by the Bureau of Labor Statistics in 1917[1] showed that there are no appreciable differences in the essential features of the national and local trade union sick benefit funds. As a rule, the amount of weekly benefit, the length of the waiting period, and the number of days for which benefits are paid are approximately the same.

It is, therefore, permissible to assume that the national or international sick benefit funds are typical of all the existing trade union funds. The remaining portion of this article will, therefore, be limited to a presentation of some facts and figures relating to the workings of the sick benefit funds maintained by the previously mentioned sixteen national or international organizations of which one is not affiliated with the American Federation of Labor.

Table II, which is based upon the results published in the cited report of 1917 made by the Federal Bureau of Labor Statistics, shows the principal provision of the existing sixteen national sick benefit funds:

TABLE II—Principal Provisions, Extents of Disability, and Per Capita Costs of Cash Benefits‡

Fund No.	Waiting period (days)	Maximum benefit period (days)	Weekly benefit (in dollars)	Aver. annual No. disability days per member (all disabilities).	Aver. annual benefits per member (in dollars).
1	7	78	$12.00	4.5	$8.94
2	1[1]	182	10.00	4.5	5.00
3	7	112	7.00	3.3	3.27
4	7	91	5.40[5]	—[2]	3.64[3]
5	7	700	5.00	—[2]	4.26
6	7	91	5.00	3.7	2.23
7	7	91	5.00	—[2]	4.32
8	7	91	5.00	3.5	2.03
9	7	42	5.00[4]	1.1	.79
10	7	70	5.00	—[2]	1.61
11	14	91	5.00	3.1	1.82
12	14	70	5.00	2.0	1.16
13	14	112	5.00	2.8	1.68
14	14	84	5.00	1.7	1.03
15	14	91	4.00	2.0	1.14
16	14	91	3.00	—[2]	1.56

1. No waiting period in cases of disability due to accidents.
2. No record.
3. This figure is different from the amount shown in the source, being based upon the reports of a later year.
4. Three dollars per week for female members.
5. This organization is now paying a weekly benefit of $7.60.

‡Source: Monthly Review, U. S. Bureau of Labor Statistics, August, 1917, page 29.

The presented Table II shows that the waiting period, in a majority of the national or international funds, is seven days, and that the maximum period for which benefits are paid is, in the bulk of instances, about thirteen weeks. More than three-fourths of the national funds pay a weekly benefit of about five dollars. The average number of disability days per member varied from 4.5, the highest to 1.1, the lowest, and was in a majority of instances about three days. It must be noted in this connection that the record upon which the figures of Table II are based contained only cases of sickness for which benefits were paid and that the figures given do not, therefore, include cases of sickness of less than the waiting period or of disability periods longer than the maximum time for which benefits are paid.

The specific arrangement of Table II was designed to correlate the extent of disability reported and cost of each fund with its principal provisions, such as (a) the length of the waiting period, (b) the maximum number of days for which benefits were paid, and (c) the amount of weekly benefits, all of the latter being shown for each fund in columns 2, 3, and 4, respectively, of the table. The last column of the table shows the *per capita* costs of the cash benefits. These costs vary naturally with the just enumerated three principal provisions of each fund. The highest *per capita* cost—$8.94—was that of fund number one, while the lowest cost—only seventy-nine cents—was found in connection with fund number nine. The average *per capita* (cost of cash benefits in the ten funds) having a waiting period of seven days was $3.61. The funds with a waiting period of fourteen days showed a *per capita* cost of $1.40.

Reports Only on Benefits Paid

Caution should be exercised in interpreting the figures shown in Table II. In considering the results of the investigation upon which the table was based, one must keep in mind some incidental factors which have a tendency to cause a wide discrepancy between the amount of disability reported for which benefits were paid, and the actual amount of disability. These factors are: (1) The length of the waiting period, that is, the number of days that must elapse before the payment of cash benefits begins; (2) the maximum number of days for which benefits are paid; (3) the amount of weekly benefit; and (4) the liberality with which the benefits are awarded. These factors must be considered in evaluating the figures presented because, as already stated, none of the trade union records examined contained any information regarding disabilities for which no benefits were paid. The statistical results arrived at, therefore, did not include cases of disability of a duration shorter than the full waiting period or of a duration longer than the maximum period for which benefits are paid.

The bearing of the waiting period upon the amount of reported sickness can hardly be underestimated. In connection with another investigation made by the United States Bureau of Labor Statistics it was found that not less than about one-fifth of all the temporary disability cases are of a duration as long as full seven days (Table III). The influence of the maximum benefit period upon the figures shown, although important enough, is much less important than that of the waiting period because the great majority of the trade union funds limit the benefit period to thirteen weeks.

The influence of the amount of benefit paid per week upon the reported amounts of disability, and upon the costs, comes about in the following manner: if the benefits paid are as large as the usual earnings of the beneficiary, or larger, an incentive to malinger is created. Small benefits have an opposite tendency. If the amount of weekly benefits paid is too small to afford actual relief, a member, though really sick, is not likely to cut off his regular income by putting himself on the sick list. This fact was brought out in connection with the mentioned partial survey made by the Bureau of Labor Statistics, in an attempt to correlate the amounts of reported sickness with the volume of employment. In this instance it was found that proportionately larger extents of disability were reported during the dull periods of the year when the earnings of the prospective beneficiaries dropped to their usual minimum.

A few words must be said regarding the sev-

TABLE III—Proportion of Cases of Specified Duration and Number of Per Cent of Disability Days§

Duration	Cases		Disability Days	
	Number	Percent of Total	Number	Percent of Total
Under 1 Week: 1 day	270	0.62	267	—[1]
Under 1 Week: 2 days	1,013	2.33	1,996	0.2

§This table, presented here by the courtesy of the United States Bureau of Labor Statistics, furnishes, perhaps, for the first time, an accurate statement as to proportion of disability cases of specified duration among wage earners. The figures given herein will appear in an early report to be published by the above mentioned Governmental agency.

eral other factors which tend to cause discrepancies between the disability reported and the actual amount of sickness. These factors are principally of an administrative and psychological character. Malingering is frequently due as much to the dishonesty of the claimant as to the liberality or carelessness of the administrative methods used in the awarding of benefits. If the payment of benefits is made in a spirit of philanthropy or charity, as was found to be the case in one of the organizations studied, many a self-respecting legitimate claimant will refrain from applying for benefits. The record of illness of such persons will, therefore, be lost. Again, as was the case in another instance, if sick benefit payments are made carelessly and without proper investigations, the number of sick persons and the length of their disability periods will show a tendency to increase. The latter statement is not intended to reflect upon the personal character of the claimants; it is merely an endeavor to bring out as clearly as possible the "natural" defects of the figures presented in Table II as well as any of the figures showing the extent of disability or maintenance costs.

The service and information branch of the office of the Surgeon General announces that there are 730 commissioned vacancies in the Medical Corps, United States Army, and for purpose of filling them examinations of all eligible applicants will be held March 15 in the United States and its colonial possessions, including Panama Canal Zone, as well as in France, Germany, and Siberia.

SURVEY TO RESULT IN MEDICAL CENTERS

The United States Public Health Service is conducting an unusually extensive survey of school and home conditions of children in several sections of Missouri. This work has been undertaken at the request of the State Board of Health with Dr. C. P. Knight, of the United States Public Health Service, in charge, assisted by Dr. Lydia A. DeVilbiss, who formerly directed the department of child hygiene in Kansas. The survey is expected to result in medical supervision of schools.

SCHOOL AND HOSPITAL AT PEKING

The Rockefeller Foundation through its subsidiary, the China Medical Board, is building in the capital of China a modern medical school and hospital together with groups of houses for members of the teaching staff. The completed plant will include laboratories for anatomy, physiology, and chemistry, a special building for pathology, a 250-bed hospital, a private patient building with twenty-seven rooms, a large out-patient department, a hospital administration unit, a nurses' home, power and gas plants, and an animal house. The faculty residences, grouped in two walled areas or "compounds," are of fireproof construction, and are supplied with every modern convenience including pure water, electric light, and fuel gas. The buildings embody certain characteristic features of Chinese architecture. The main roofs and the pent roofs are covered with glazed green tile made in one of the Imperial tile factories. The eaves and porticoes are embellished with gaily painted decorations in red, blue,

Members of the construction group and teaching staff of the Peking Union Medical College assembled before a partly completed entrance of the new medical school being erected by the Rockefeller Foundation, through the China Medical Board.

green, and gold. The Chinese have already christened the group of buildings "The Green City." Three of the teaching laboratories were occupied October 1, 1919. It is expected that the entire plant will be completed by January 1, 1921.

THE SERVICE OF THE DISPENSARY*

A Report by the Public Health Committee of the New York Academy of Medicine, New York City.

A. Preface

Even if the hospitals of the country were adequate in number and equipment to take care of all patients requiring hospital care, the number of such patients would not serve as an index of the medical service necessary, and the neglect of dispensary care for ambulatory cases and for out-patient work would not only cripple the hospital activities, but would make inoperative one of the chief means of placing prevention as well as cure of disease within the reach of all classes of society.

The significance of the rapid growth of the dispensary, its importance in the administration of medical care, and its tendency to organize in the interest of better service to the masses all those specialties of medicine which would not otherwise be available, are attracting increasing attention, and the development of this form of service would seem to indicate that it is the function of the dispensary to cover the major portion of medical service. A survey of existing dispensaries and an estimate of their relative efficiency become essential to their supervision and standardization.

The study presented herewith of the dispensaries of New York City is perhaps the most intensive yet undertaken in this field.

I. The Growth of the Dispensary

The growth of the dispensary in the last twenty years has been phenomenal. While, according to the United States Bureau of the Census,[1] there were 154 dispensaries in the United States in 1904, the total number of dispensaries in the country at present is approximated at 3,000.[2]

In their annual report for 1918 the State Board of Charities of New York made the statement that "few of our social institutions are increasing in number and importance more rapidly than the dispensaries." In this state there were, in 1918, 213 dispensaries, of which 153 were in New York City. The increase in dispensary facilities has been due largely to the establishment of tuberculosis, dental, industrial, and other types of special clinics, and was occasioned chiefly by the extension of the public health movement. Table I, comparing the numbers of the several types of dispensaries in the state of New York in 1908 and 1918, shows how the relative percentage of the general dispensaries has decreased from 79 per cent to 53 per cent, while the tuberculosis, dental, and other special clinics have increased manifoldly in relative importance.

II. Dispensary Facilities in New York City

According to official figures, there are 153 dispensaries in New York City. In this number are included 21 tuberculosis, 8 dental, 10 eye, and 3 rabies clinics of the Department of Health, and the 6 school dental clinics maintained by the Children's Aid Society. Of the 105 dispensaries outside of the Health Department and School Dental Clinics, there are 65 out-patient departments of hospitals, 34 detached dispensaries, and 6 college dispensaries. In addition to the above mentioned clinics listed

*The first of a series of three articles on dispensary service which will appear in successive issues of Modern Medicine. "The Problem of Disease" will be discussed in May, and "Dispensary Patients" in the June issue.

1. "Benevolent Institutions 1904," Special Report of the United States Bureau of the Census, Washington, 1905, pp. 36-37.
2. Davis and Warner, "Dispensaries," The Macmillan Co., New York, 1918, p 37.

by the State Board of Charities, the Health Department maintains 12 venereal disease clinics—all but 2 advisory only—3 occupational clinics for the examination of food handlers prior to issuing licenses, and 60 baby welfare stations. There are several private agencies maintaining milk stations for children.

As seen from Table II, compiled on the basis of information received from the dispensaries, the dispensaries are open weekly for 7,932½ hours and hold 3,680 sessions per week, the average length of each session being more than two hours The number of evening clinics is comparatively very small. The total number of evening clinic hours amounts to 213½, or a little more than 2.5 per cent of the total number of clinic hours per week.

The largest number of clinic hours weekly is given by the departments of internal medicine,—1,078 hours weekly, or 13.6 per cent of the total clinic hours. The surgical clinics offer their facilities for 879½ hours weekly, or 11.1 per cent of the total number of clinic hours; and the pediatric clinics, exclusive of the baby welfare stations of the Health Department, are open 599 hours, or 7.5 per cent of the total time now given by the dispensaries each week. Gynecology, eye, dental, ear, throat, tuberculosis, nose, genito-urinary diseases, dermatology and syphilis, orthopedics, and neurology supply, in the order named, practically the whole of the remainder of the clinic facilities.

The magnitude of the dispensary service in New York City is perhaps best illustrated by the figures of the number of persons treated and the number of treatments given at the several institutions annually.

Table III, obtained through the courtesy of the State Board of Charities, shows that the average number of persons treated in the dispensaries of New York has been more than one and one-fourth millions annually for the last five years, and the number of treatments exceeded four millions annually, making an average of more than three treatments per person.

TABLE III—Dispensary Service in New York City, 1913-1918, Inclusive—New York City Boroughs

Number of Persons Treated in Dispensaries

Year	Manhattan	Brooklyn	Bronx Queens Richmond	Total New York City	Average No. of Visits

*Nine months.

The number of persons treated in dispensaries, as shown by Table III, is considerably in excess of the actual number of persons using the dispensaries, because in the course of a year a large number of dispensary patients register more than once in the same dispensary for different conditions, and some in more than one dispensary for the same condition. As only several dispensaries publish in their annual reports the distribution of patients and of attendance by clinic departments, it was possible to obtain this information in but a fragmentary way. According to the available statistics, about 20 per cent of the new patients are referred to the departments of internal medicine (Table II) and a little more than 14 per cent of the total number of consultations are given in those departments; about 13 per cent of new patients are admitted to the departments of surgery, to which 16 per cent of the total visits to the dispensary are credited. About 11 per cent of the new patients come to the pediatric clinics, where more than 9 per cent of the total consultations in the dispensaries are recorded. The eye, ear, nose, and throat departments receive 22.9 per cent of the new patients and give 19 per cent of all the consultations. Gynecology and genito-urinary disease departments receive 5.5 per cent of the new patients, and record 10.3 per cent of the dispensary attendance. The other special departments receive the remainder of the patients. A similar clinic distribution of patients is found in dispensaries of other large cities.

The distribution of the patients among the several departments of the dispensaries is significant. It indicates that only one-fifth of the patients are taken care of in the department of internal medicine, that less than one-eighth of all the patients come to the departments of surgery, one-ninth of them to the departments of pediatrics, and the rest, or almost 58 per cent of patients, are distributed among the several specialties. In other words, 80 per cent of the dispensary patients come with complaints which are being taken care of in departments other than that of internal medicine. This is equivalent to saying that by a process of evolution conditioned by economic, medical, and public health forces, the dispensary has become an institution to which a large part of the wage earning class of our population resorts when in need of services of specialists, or of a special examination or treatment, which in the majority of instances they cannot obtain except at the dispensary.

The recognition of this condition calls for a reconsideration of the whole dispensary problem from the standpoints of economics, administrative policy, and the relation of the medical profession to the dispensary. Intimately bound up with any plan of reform of the existing practices that might be undertaken is the question of dispensary fees and that of "pay clinics."

III. The Dispensary Law

The New York Law defines a dispensary to be "any person, corporation, institution, association, or agent whose purpose it is, either independently or in connection with any other purpose, to furnish at any place or places, to persons non-resident therein, either gratuitously or for a compensation, determined without reference to the value of the thing furnished, medical or surgical advice or treatment, medicine or apparatus, provided, however, that the moneys used by and for the purposes of said dispensary shall be derived wholly or in part from trust funds, public moneys, or sources other than the individuals constituting said dispensary and the persons actually engaged in the distribution of charities of said dispensary." By this definition a dispensary continues to function legally as long as the fees charged do not bear any relation to the services rendered. As long as the dispensary gives services free to those who cannot pay, and as long as the physicians in the dispensary work without pay or for a purely nominal compensation, the dispensary fees, even if increased considerably, will still bear no relation to the value of the services rendered. There is one institution in this city devoted to the treatment of special conditions which charges an admission fee of one dollar in the out-patient department.

Even the so-called pay clinics, which are theoretically supposed to be self-supporting, do not as a rule include in their charges interest on the investment represented by the institution, or capital, corporation and other expenses, and therefore come within the legal definition of a dispensary.

It would be well to have a clear ruling on the matter by the State Board of Charities and, if need be, the existing law should be so amended as to make no difficulty whatsoever in the promotion of pay clinics, which are urgently needed. Under existing conditions those unable to pay the customary fees of specialists or to meet the expense of laboratory and x-ray examinations and of special treatment are compelled to resort to the dispensaries, although they may be in a position and willing to defray a part of the costs prevailing in private practice.

It is a misdemeanor to obtain medical or surgical treatment in a dispensary under false representation, and it was with the intention to facilitate legal action against violation of this law that patients who looked as if they were able to pay a physician were required to sign a "representation card" on which certain statements about their occupation, income, and ability to pay for the services of a physician had to be made and signed by the applicant. Because of the numbers to be admitted, or for other reasons, few dispensaries made effective use of this card[3] and the requirement for the "representation card" was omitted from the revised rules of the State Board of Charities. Although the law has been on the statute books since April 18, 1899, no case of abuse of the dispensary has been brought to court.

In spite of the rapid growth of the dispensaries throughout the country, there are very few states which have adequate laws concerning the dispensaries. The licensing of dispensaries and the inspection of dispensaries, even if required, are, in some states, not carried out on account of inadequate appropriations for the purpose.

The most comprehensive laws on the subject are those of New York and of Massachusetts. Under the Massachusetts Law, which went into effect on April 2, 1918, the licensing of all dispensaries, except the state and municipal, is placed in the State Department of Health, and the Public Health Council of the department is charged with making rules and regulations for the conduct of dispensaries. Likewise, the State Health Department has the authority to visit and inspect any dispensary at any time in order to ascertain whether it is licensed and conducted in compliance with the law and rules and regulations established.

The Control of Dispensaries

The New York Law, enacted in April, 1899, places the licensing and control of dispensaries in the hands of the State Board of Charities. The Board has the power "to make rules and regulations, alter or amend the same, in accordance with which all dispensaries shall furnish to applicants, medical or surgical relief, advice or treatment; medicine, or apparatus." The Board may at any time inspect the dispensaries to ascertain if they are conducted in compliance with the law and the regulations of the Board. The Board has the right to revoke a license.

Violations of the law, or of the rules and regulations of the Board, are deemed to be a misdemeanor.[4]

The rules were amended in June, 1918, and became effective on July 1 of that year. Under the present rules the admission of the patient is left to the discretion of the admitting officer, who is required to question each patient about his financial status, and if an investigation is made, the result of it must be filed among the permanent records of the dispensary. The exemptions from this provision have been extended. As the rule now stands, the groups of patients that may use the dispensary without regard to their financial status are: (1) Emergency cases; (2) patients who are received in dispensaries connected with medical schools and are selected for use in clinical instruction; and (3) patients treated for communicable diseases. This last applies chiefly to tuberculosis and the venereal diseases because of the public health aspect involved in the control and treatment of these maladies.

The amended rules further provide that the license certificate of the dispensary must be posted in the waiting room; that on discharge of a patient "a record shall be made of the results of treatment as far as they can be ascertained"; and that a record of the time of arrival and of departure of each physician be kept at each institution. The other changes in the rules refer to the presence of a woman at obstetrical and gynecological examinations, and to the provision of a nursing service in all dispensaries receiving and treating cases of pulmonary tuberculosis.

The ratings given to the dispensaries by the State Board of Charities, and the shortcomings pointed out on inspections made by the agents of the Board, stimulate the institutions to ameliorate existing conditions. The inspections, however, have often been of a perfunctory character and have not commanded the degree of attention on the part of the institutions which they would if made by competent investigators. Conditions have changed for the better in that respect, and it is to be desired that the State Board of Charities designate for this task of inspection a corps of well trained and well compensated officers, whose inspections would be thorough and their suggestions based on an understanding of proper standards of dispensary equipment and procedure. The present practice of the State Civil Service Commission in not differentiating among the various kinds of inspections which the State Board of Charities has to perform makes it difficult for the Board of Charities to obtain inspectors trained in the understanding of hospital problems and procedure, as the prescribed qualifications are the same for inspection of all kinds.

IV. Responsibilities of Dispensaries

It is impossible to obtain exact figures as to the amount of investment the dispensaries of New York City represent. It undoubtedly amounts to many millions. Likewise, no exact information is available with regard to the total cost of administration and maintenance of our dispensaries. The United Hospital Fund of New York gives statistics of the expenses of thirty-four dispensaries. The total reported expenditures for the year 1918 amounted to approximately $700,000. On this basis a conservative estimate of the expenses of all the dispensaries would be at least two million dollars per annum. Institutions expending such considerable sums of public or corporate funds have definite responsibilities. These responsibilities are toward the community which supports the institution, as well as toward the patient who should be assured efficient medical treatment, and toward the physicians and other workers in the dispensary, who should be afforded opportunity for training and for advancement in recogni-

3. Annual Report of the New York State Board of Charities, 1918, p. 202.

4. The law relating to dispensaries constitutes Article XV, Chapter 55 of the Consolidated Laws of the State of New York, paragraphs 290 to 296, inclusive.

tion of their services. The responsibilities of the dispensaries have in many instances not been fully realized, nor have their opportunities that lie in the fields of prevention of disease as well as in the amelioration of social conditions, been appreciated, although the possibilities along these lines were pointed out half a century ago.

In May, 1868, the *New York Evening Post* published an account of the dispensaries in New York City, giving a brief history of their development, management, and economic value, which concluded in the following manner:

"The dispensaries do their greatest service in the prevention of diseases. The patients they care for form but a small part of their annual reports; those they assist in escaping a long and lingering sickness are by far the greater part of the whole number treated. The promptness with which aid reaches the sick poor is the crowning glory of the system. Disease is treated in its incipient stages, and death held at bay beyond the threshold of many a crowded tenement by the immediate attention patients are able to get through this system. . . . The dispensaries are boards of health in miniature averting thousands of physical ills, quietly and unostentatiously, that could never be reached in any other way. They were organized to benefit the poor; but, like all successful efforts to improve the condition of a single class, it has been found that their blessings fall, in a different form, upon all other classes."

At the time this was written there were in New York City but few dispensaries, and their work in the field of disease prevention lay chiefly in vaccinations against smallpox. With the increased opportunities at command at the present time in the field of both preventive and curative medicine, the responsibilities of the dispensaries have increased many fold. They can become institutions for efficient medical diagnosis and treatment, public health centers in their respective neighborhoods, and can afford valuable training facilities to physicians, nurses, and social service workers.

V. The Scope of the Study

It was the recognition of the prevailing failure on the part of the dispensaries to develop to the fullest extent their medical and educational resources—a condition which was accentuated during the period of the war—that prompted the Public Health Committee of the New York Academy of Medicine to undertake the present study.

It was the aim of the Committee to present as accurate data as could be secured relating to the medical and social service work in the dispensaries, the existing facilities in equipment and personnel, the prevailing methods of organization and administration, as well as the financial resources of the institutions; and on the basis of the ascertained facts to suggest methods of rendering the work of the dispensaries more efficient and valuable.

VI. The Method of the Study

The available information concerning dispensaries was thoroughly examined prior to undertaking the survey in July, 1918.

The excellent work of the Associated Out-Patient Clinics of the City of New York has been of great assistance in the present study. It was unnecessary for the Committee to undertake the formulation of standards of equipment and organization of the various branches of dispensary service, because this had been done in great detail by the Association, which also has contributed greatly toward a proper understanding of the underlying problems of dispensary management.

It was also thought unnecessary to include in the survey all the institutions of the city. An attempt to do this would have prolonged unduly the period of the inquiry, and the information gathered, although greater in amount, would not have added materially to the comprehension of dispensary conditions. It was therefore considered advisable to limit the study to about forty-five of the most important institutions, doing the bulk of the dispensary work of the city and representing the various classes of dispensaries so far as affiliation and type, size, and excellence of service are concerned.

The study is aimed to be intensive rather than extensive, and the Committee feel that by the method chosen they have been enabled to elicit facts in a way that has never been attempted before, in this city or elsewhere.

The study resolves itself into six major parts: (1) Organization and administration of dispensaries; (2) medical work; (3) social service; (4) finance and accounting; (5) economic status of patients; and (6) the relation of the dispensary to the problem of disease in the city.

Organization and Administration

Data bearing on the following subjects have been analyzed under this heading: the type of dispensary organization and affiliation; the methods of appointment of physicians, their compensation, and the relation of dispensary physicians to the hospital; the admission and distribution of patients; the arrangement of dispensary rooms; the equipment of dispensaries, including facilities for laboratory and x-ray work, as well as for special therapy; the keeping and filing of records; the cleanliness of the dispensary; courtesy on the part of employees, and similar matters pertaining to organization and administration.

Medical Work

The study of medical work was made entirely on the basis of records. This was the only objective manner in which it could be made. Such a method has its recognized shortcomings, but is of distinct value for comparative purposes, particularly when it is based, as is this, on thousands of records of not only the average run of cases, but, also, of selected diseases of a chronic type which require a protracted course of treatment. As this part of the study was made in 1918, it was thought that utilization of current records would lay the findings open to the criticism that the records of 1918 did not reflect the character of the work as carried on under normal conditions. To obviate this possible criticism records were selected pertaining to the first three months of 1917, that is, prior to our entrance into the war; in addition, a certain number of records were taken for the same months of 1918, in order that by a comparison the difference between a normal and abnormal year could be ascertained. Special studies were made of the tuberculosis and venereal disease clinics because of the particular health aspect involved.

Social Service

The procedure in referring patients to the social service departments and the technic of social service work has been studied in detail; likewise the organization and needs of the social service departments. Recognizing the importance of this new branch of dispensary service, a great deal of time and attention have been given to this part of the study.

Finance and Accounting

An expert in bookkeeping was engaged to make a study of the prevailing methods of dispensary accounting, which

in a very large number of instances was found to be carried on in an inaccurate and unscientific manner.

Economic Status of Patients

A large number of dispensary patients were interviewed at the dispensary, and one-third of them visited later in their homes and reasons for applying to dispensaries were ascertained, as well as their financial resources. The information gathered has been tabulated so as to show the weekly income of the families on a unit basis and by nationalities. The duration and mode of treatment of various conditions prior to applying to the dispensary were ascertained, as well as the degree of incapacity at time of such application of dispensary patients, their occupation and their home conditions.

Relation of Dispensary to Problem of Disease

Analysis of the economic status of dispensary patients was supplemented by a larger study bearing on relation of the prevalence of illness to the type of medical service which is employed by the several economic and racial groups of our city population. In order to ascertain this information a house-to-house canvass of selected blocks in the various parts of the city was made; 2,023 families were visited. Information concerning the amount of sickness was secured, not only during the time of the visits, which were made in January, February, and March, 1919, but also for the entire year 1918.

The investigators were requested to note in each instance whether the heads of the families visited were able to speak the English language and how long they had lived in the United States, with a view of correlating the type of medical service sought to the ability to speak English and to the degree of adaptation to American life.

LAW FOR THE DOCTOR

By LESLIE CHILDS, Attorney at Law, Indianapolis, Indiana*

The Application of a Domestic Remedy for a Fee as Practising Medicine.

One Joseph Huff, a farmer, was indicted under the Kansas statute for the regulation of the practice of medicine, for practising medicine without a license. Huff was convicted in the lower court and prosecuted an appeal to the Supreme court. The case is entitled State of Kansas *vs.* Joseph Huff, 96 Kan. 632, and the facts upon which the indictment was predicated were in substance as follows:

Huff claimed that he had discovered a remedy for cancer. This alleged remedy was manufactured by him from vegetables grown on his farm, and at the time of his trial he stated that he had treated from fifty to seventy-five different patients. One of the patients was a Mrs. Stewart, who was named in the indictment.

The evidence tended to show that he treated Mrs. Stewart under a contract by the terms of which he was to receive one hundred dollars. He had received fifty dollars of this amount when indicted, and was to have been paid the balance when a cure had been effected. In describing his method of treatment the defendant said:

"I take a little stick and get a little medicine on it and put it on the cancer, the diseased part, and that works from fifteen minutes to half an hour, until it works the strength out of the medicine, and I then clean that off and apply it again." The report fails to show how efficacious this treatment was, and is taken up with a discussion of the question as to whether, under the Kansas act, this application of a domestic remedy for a fee amounted to a violation of the statute in question.

The section of the act under which the indictment was laid reads in part as follows: ". . . any person who shall practise medicine . . . in the state of Kansas without having received and recorded a certificate under the provision of this Act, . . . shall be deemed guilty of a misdemeanor.

"Any person shall be regarded as practising medicine and surgery, within the meaning of this Act, who shall prescribe, or who shall recommend for a fee, for the like use, of any drug or medicine. . . . This Act shall not apply to any commissioned medical officer of the United States Army, Navy, or Marine service, . . . nor shall anything in this Act apply to the administration of domestic medicines, nor to prohibit gratuitous services."

In the defendant's appeal to the Supreme Court, he assigned a number of technical errors, alleged to have been committed in the lower Court, which were over-ruled. The most important error assigned, in so far as this article is concerned, was one on an instruction given by the lower Court in respect to the scope of the term, "administration of domestic medicines."

The lower Court instructed the jury that, "the term 'domestic medicine,' as used in this Law, means medicine as practised by unprofessional persons in their own families or households." The Supreme Court reviewed the authorities at length to determine whether the defendant could have been prejudiced by this instruction. In conclusion it was stated:

"A non-professional person is permitted, under the Law, to administer domestic medicines, but not to take pay for recommending their use. The theory of the state is that one who proposes to ask and receive compensation for advice as to the use of medicines thereby holds himself out as possessed of special and peculiar information on the subject, and that it is the province of the state to see that he possesses it, or, in default of proof thereof, to prevent his making the unfounded claim a source of revenue. . . . Under the defendant's own statement, he was guilty of the offense charged against him, if for a fee he recommended the use of his medicine as a remedy for cancer, whether it was a 'domestic medicine' or not."

Holding that under the Kansas Act it was not material whether the medicine was a domestic medicine or not, where it had been prescribed for a fee. For, granting it to be a domestic medicine, that fact would not constitute a defense. The judgment of conviction rendered in the lower court was thereupon affirmed.

*The eleventh of a series of articles on "Law for the Doctor," written for MODERN MEDICINE by Leslie Childs.

TRACHOMA PROBLEM IN OHIO

As a rule, health officers do not consider that treatment is not a proper function of the health department, but this they believe does not apply to trachoma.

Trachoma is a dangerous, contagious disease of the eyes which in early cases may be easily cured by simple operative procedures. In order to discover cases when they can be cured and before they have transmitted the disease to others, extensive surveys must be made.

The reported cases in Ohio number 2,037. Surveys of eye conditions among school children have been made and others are planned. The staff of the State Department of Health now includes a chief, Bureau of Trachoma Clinics, and a trachoma nurse. It is expected that the special trachoma campaign undertaken with the help of the United States Public Health Service will within a few years wipe out the menace in Ohio.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

SOME FACTS ABOUT PUBLIC HEALTH NURSING

MOST phases of public health originate with the medical profession. Some have been given a decided impetus by being correctly interpreted to the public by a group of messengers known as public health nurses.

Dr. C.-E. A. Winslow has said, "The nurse is the central figure in the modern public health campaign. The main object of the campaign is the training of the individual in laws of personal hygiene and public sanitation, and it is the nurse who brings those laws in effective form to the factory and to the tenement dwelling where they must be applied."

Until now, medical science has found no better way to speak to people, no better point of attack, than through the nurse whose entrance into the home is acceptable and desired. There is no greater factor in the control of disease than the care and instruction given by the nurse to so many individuals.

Public Health Nurse Qualifications

The public health nurse must be a graduate of a recognized hospital. She should have had some work in public health during her hospital training or additional training after graduation. The usual hospital course of two or three years does not fit her to cope with the social and economic problems which constitute a large part of the daily responsibility of the public health nurse. She lacks fundamental knowledge of health administration and social service without this special training, and it is difficult for her to do practical work without the apparatus to which she has become accustomed in the hospital.

Because of her entrance into so many types of homes, where the friendliness and receptivity on the part of the families afford her a wonderful opportunity to teach, the public health nurse must possess a distinct personality, one that is able to successfully meet any and all demands of her profession.

History of Public Health Nursing

The history of public health nursing is briefly summarized in a leaflet recently distributed by the National Organization for Public Health Nursing, as follows:

"The first public health nurses were the nuns and sisters of the early Church. When the Council of Trent ordered that all communities of women be enclosed, visiting nurse work was given up. St. Vincent de Paul, in the middle of the seventeenth century, founded the order of the Sisters of Charity for visiting nurses. 'Nuns,' he said, 'must needs have a cloister, but the Sister of Charity must go everywhere—her monastery the house of the sick, her cell the chamber of suffering, her cloister the streets of the city.'"

This work was so well founded that it exists to this day, the Sisters of Charity conducting training schools for nurses and doing visiting nursing in the homes of the poor in some of the cities of the Old World.

Visiting Nursing Societies were introduced in Boston, Philadelphia, and Chicago, 1886-09. The first municipal nurse employed in Los Angeles entered upon her duties in 1898. School nursing was started in New York in 1902, and rural nursing was begun by the Red Cross in 1912. England was the first country to develop public health nursing, and South Africa, Australia, and Canada have introduced this service widely. The war has introduced public health nursing, as we know it, in Italy and France. In Cuba, a corps of visiting sanitary nurses constitute a special service under the Cuban Department of Health, while in Japan public health nursing is being begun by a Japanese woman who came to America for the purpose of taking her training in the Woman's Hospital and in the Henry Street Settlement of New York.

This new but rapidly developing type of nursing started with bedside care of the sick poor in homes. It now continues to nurse the sick, but it is constantly striving to prevent further sickness and to promote general well-being. There are over 2,537 associations doing this kind of work, and over 6,000 nurses engaged in it.

Many nurses are specializing in infant welfare, tuberculosis, industrial, maternity, mental, school, or social work, but the nurse working alone in a small community or a rural section usually combines all these phases of public health nursing. They are employed by boards of health, philanthropic organizations, school boards, county boards of supervisors, industries, insurance companies, and many other agencies. The ultimate goal should be to make public health nursing a public charge. It is false and undemocratic to coddle it, beyond its demonstration period, merely for the sake of protecting it from politics. There are many ways in which the standards which have been built up so painstakingly may be guarded.

Public health nurses are known as community nurses, county nurses, visiting nurses, district nurses, teachers of hygiene, industrial welfare, or social service workers, often taking their name from the organization supporting the work, as, tuberculosis or infant welfare work.

What Public Health Nurses Are Doing

1. *The Visiting Nurse.*—Statistics show that only 10 per cent of our sick are cared for in hospitals, 90 per cent remaining in their homes. Since sickness causes 75 per cent of the poverty in existence, only a small proportion of people are able to employ private nurses. Every year visiting nurses are caring for larger numbers of sick in their homes, and in this manner are materially reducing poverty.

A recent study of the Metropolitan Life Insurance Company, covering five years previous and five years subsequent to the introduction of the service, proved, that, in the million cases studied, visiting nurses had reduced the mortality rate 12.8 per cent, bringing about a tremendous saving in life, a shortening of periods of illness and suffering, and an increased earning capacity.

2. *The Infant Welfare Nurse.*—The infant welfare nurse is truly a saver of lives. By systematically visiting the babies of her community or district, by helping with care and instruction when they are sick, and by constant vigil and advice when they are well, the infant welfare nurse undoubtedly lowers the death rate and lessens the awful wastage from crippling and maiming of young life by illness.

She works in the home, in clinics, in milk stations, in health stations, and with boards of health. Through conferences, through weighing and measuring babies, through mothers' meetings, and through talks to clubs and Little Mothers' Leagues in the schools, she prepares for the coming generations.

Infant Care Lessens Mortality

New York City, in ten years, reduced its infant mortality from 186 deaths per 1,000 babies to 86, largely through the work of the nurses. Dr. C.-E. A. Winslow says, "The proportion of young babies that will die depends almost wholly on the amount their mothers know about infant care. In Russia, one baby in every four dies before completing the first year of life. The Russian mothers love their babies, but the 'mother instinct' does not teach them to feed them only on mother's milk or clean, pasteurized cow's milk and so they give those babies other foods and the babies are killed by summer diarrhea. In the United States, about one baby in eight dies before reaching its first birthday. That is better than the Russian record; but in New Zealand only one baby out of twenty dies in the first year of life. The New Zealand mothers are no more devoted than ours. They are no more highly educated nor any wiser in most matters, but they have learned more about infant care."

We have lately realized that the importance of the period between infancy and school age has, for a good many years, been overlooked by public health nurses. But now we find that infant welfare nurses have, as a rule, throughout the country, undertaken to care for children up to the age of five years. They are doing much to prevent the terrible toll of child life during the period when children are most susceptible to communicable diseases; when their bones are soft and easily bent; when stomach trouble so often occurs as a result of improper feeding and the decay of the first teeth.

3. *The Prenatal and Obstetrical Nurse.*—The prenatal and obstetrical nurse often continues her work with the infant welfare nursing. She visits and advises mothers before the birth of the baby and sees that the mother gets the proper prenatal and post-partum care.

Recently, special studies have been made in connection with the Federal Children's Bureau in regard to the number of deaths from childbirth. Fifteen thousand mothers die yearly in the United States. The death rate from childbirth between the ages of 15 and 45 years was greater than the mortality from any disease, with the exception of tuberculosis. A recent study of this type of

nursing in Boston, with 731 cases, shows that with proper medical and nursing supervision before birth the death rate of babies during the first year of life has been cut in half and, during the second year, reduced by one-third. Still-births have been decreased by one-half, as well as maternal mortality.

4. *The School Nurse.*—The school nurse assists the school doctor in his medical inspection of children. She carries his advice to the parents in the homes and sees that treatment is secured. She does much to prevent the spread of disease by teaching the children personal hygiene. She advises the mother of the undernourished child. By frequent inspection of the children, she discovers decayed teeth, enlarged tonsils, adenoids, unclean heads, and other conditions often found which are detrimental to good health, good spirits, and good school work.

5. *Hospital Social Service Nurse.*—The medical social service nurse forms the connecting link between the hospital or dispensary and the home. By visiting the patient in his home after hospital or dispensary treatment she can interpret the doctor's orders so as to secure the desired results. Very often she is able to remedy social conditions which have caused the illness and might prevent convalescence and recovery. Frequently she finds occupation for the discharged patient and insures the proper care of children. This work is of paramount importance at the present time, when the high cost of living is causing so much illness and distress in homes of the poor, and even of the middle class.

6. *The Industrial Nurse.*—It has been said that every day in the year 2 per cent of all workers are incapacitated for work by illness. The industrial nurse attends to minor accidents and injuries incurred by the employees during the day's work.

She cooperates with the employers and employees to establish the best possible conditions —good lighting, ventilation, work hours, meal hours, and recreational facilities. She endeavors to have good food supplied the employees at reasonable prices. She visits the employees to give them nursing care when they are ill. She endeavors to bring about sanitary living conditions and a friendly community spirit. The industrial nurse has made a place for herself in factory, store, mine, and mill.

7. *The Mental Nurse.*—The field of mental nursing is becoming very important. The problem of mental disease and defect is being met by a campaign of education of the public by the physicians, the nurses, and social workers.

Many nurses who went abroad to care for psychoneurotic and other mental and nervous conditions are returning prepared to take up the Social Service work so necessary to our mental and nervous hospitals. All patients discharged from state mental hospitals should be followed up by a psychiatric social service worker. Nurses are assisting these patients during their period of readjustment, often preventing recurrence.

Public health nurses are doing much to promote sound mental health as well as sound physical health. Their knowledge of symptoms enables them to secure cases in the early stages, thus preventing actual breakdowns.

8. *The Tuberculosis Nurse.*—Public health nurses often specialize in caring for suspected and actual cases of tuberculosis and those who have been exposed to the disease, but the inherent nature of the work necessitates other kinds of nursing for preventive purposes, such as infant welfare, pre-school, and school nursing, in order to bring the case to the attention of the family and physician and secure treatment for the patient in the earliest stage of the disease, while there is yet opportunity for a cure.

The Tuberculosis Nurse assists the doctor at clinics to which she has persuaded suspected cases and those exposed to the disease to come. She carries into the homes instruction and advice and urges the close following of the doctor's orders. She gives nursing care in the home or arranges to have the patient cared for in a hospital, protecting the rest of the family in all possible ways.

9. *The Rural Nurse.*—The nurse working in a rural section must usually be, besides a nurse, a teacher of health and a lecturer. She is more often than not the only social worker in the county. She visits the mothers' pension and other similar cases, the county poor, the almshouse, and the jail.

Her greatest effort must be centered on the prevention of disease. She visits all the little rural schools, where she is usually responsible for the inspection of the children and the notifying of parents concerning physical defects found. She instructs the pregnant women. She watches the growing babies, and the cases of tuberculosis.

Whenever and wherever possible she gives to school children, Ladies' Aids, and county clubs, the short talks and demonstrations of home nursing, health hints, and rural sanitation, so needed and desired by rural mothers.

In succeeding numbers of MODERN MEDICINE, the editor of this department will publish longer,

illustrated articles on all of the above types of public health nursing. These articles will be written by nurses of recognized authority in their special fields. EDITOR.

CAN YOU AFFORD TO MISS IT?

THE First Biennial Convention of the National Organization for Public Health Nursing is to be held this year at Atlanta, Ga., April 12-17. A glance at the tentative schedule, however, shows that the week's program of joint meetings with the American Nursing Association and the League of Nursing Education makes it necessary to arrange for section meetings to take place April 9 and 10, the two days immediately preceding the convention.

At these meetings it is planned to organize formal sections of Industrial Nursing, School Work, and Infant Welfare, adopting at the same time their own by-laws, and electing officers. The object of these sections is the formulation and maintenance of high standards for nursing service in these three fields of public health work.

As this convention will be of special interest to all groups of nurses, private, institutional, and public health, announcement of the meeting is made at an early date, in order that hospital boards, Visiting Nurse Associations, and public health officers may have full time to arrange to send as many delegates as possible, that they may bring back to the other nurses a message of inspiration and encouragement from the meeting.

WHY A PUBLIC HEALTH NURSE?

BY GERTRUDE M. RINES, R.N., STATE SUPERVISING NURSE OF SOUTH DAKOTA, ARMOUR, S. D.

Public Health is an indispensable asset in the progress of any nation, and its attainment an object of the first magnitude. The more protection a people are offered, the more rapidly do they advance in civilization, learning, and culture; and the ravages and misery from catastrophe and pestilence will be correspondingly less. This not only applies to the masses, but to the individual. We have read and discussed and also taken steps toward bettering conditions in the large cities, but as yet very little has been done to insure better health conditions in the urban and rural districts.

Fig. 1. The nurse is teaching the mother how to protect the rest of the family from influenza through the use of the cornucopia in which to receive the papers used for the sputum of the patient.

In the past the health of the people in rural communities has not been as good as it should be. The majority of country people think as their life is rather secluded and so much in the open they cannot help but keep well. This sort of life does contribute toward the health of people, but there are other things to be considered.

Results of the physical examination of draftees in the United States Army show that the conditions of the men who came from the rural districts present a higher percentage of physical defects than do city boys.

It is also to be noted while we are considering the conditions found among the boys in the United States Army, that all of these boys are in the prime of life, and that they naturally are better qualified physically than people of any other age group.

When it is realized that the United States Army struck out every third man because of physical defects, it means that at least one-third of the people are physically defective. The majority of defects found by the United States Army have been traced back and found to be existent in the children of today. This was corroborated in one of the counties of South Dakota during the past month when the physician and public health nurse, after examination of a group of children, found defective vision, hearing, teeth, throat, and malnutrition—which is one of the greatest causes of tuberculosis, flatfootedness, and weak hearts—to exist in similar proportion as they did in men examined for army service.

The efficiency of a nation depends largely upon the health of its people. As Emerson has said, "The first wealth is health." It is utterly impossible for any individual, state, or nation to accomplish really great things without good health; for

what affects one individual comes in time to affect many, and it follows that community health work is not altogether a national problem, but a community and individual responsibility.

Health education should begin in childhood. If all parents and teachers were wise in regard

Fig. 2. The County Nurse Law has made it possible to bring to the bedside of the sick child at home the safety afforded by daily scientific care.

to health matters, it would not be necessary to bring into a community or school a specialized health worker; but very few people are familiar with the right kind of health work needed for the public.

Health Factors Studied

The public health nurse has been doing work in the larger cities for years, visiting the sick in their homes, giving general bedside care, and visiting the schools. Wherever it is possible, the nurse secures the services of a physician to help with the physical examination of school children; but many times she is obliged to carry on this examination herself. She examines the condition of school buildings, outhouses, and general sanitary conditions.

One of the biggest fields for the community nurse is the saving of babies' lives, and it is here, perhaps, that the mother needs her most. The visiting or public health nurse has proved herself the most efficient agent for the all important work of locating and looking after cases of tuberculosis in any community.

The whole trend of modern medical science is toward the prevention of disease, and the Public Health Nurse is regarded by medical science as the most competent single agent in this work of interesting the public in health education; for, after all, the prevention of an ill is much greater than its cure, and the greatest thing that is being accomplished today in a scientific way is teaching people how to live.

Through the cooperation of the County Health Officer, the County Public Health Nurse can help trace the origin of communicable diseases, and particularly tuberculosis, which is our most serious national problem.

Smallpox, which exists in nearly every county in South Dakota, is increasing and not decreasing, because of the indifference and ignorance of the people as a whole. At one time many of these cases were of a malignant type, and the mortality rate high; but since the disease is now of a milder type, people do not fear it and allow it to continue ignoring the fact that even in a mild form it invariably leaves complications. Smallpox or any other communicable disease existing in a community for any length of time, is a hindrance to the progress and efficiency of that community, and the public health nurse becomes absolutely necessary in a community to help suppress communicable diseases.

In 1915 the first public health nurse came to South Dakota to spend a month or two in several counties where an adequate number of Red Cross seals were sold in order to pay her salary. The author was the fourth public health nurse in the state, which at the present time has twenty-six public health nurses. Some are county nurses supported by county boards of commissioners, city school nurses supported by boards of education, and some are being supported by Red Cross Chapters. Sixteen of these services were inaugurated by the Red Cross Seal Commission of South Dakota. At the present time there are at least thirty counties on the waiting list for a nurse.

Fig. 3. In the Child Welfare work precision is emphasized by the nurse, and actual demonstration made in the preparation and handling of the food for the baby.

Surrounding states, Iowa, Wisconsin, and Illi-

nois, have public health nurses in nearly every county. In 1919 health laws passed the legislature in seven states, making physical education, training, and examination of school children compulsory.

Health Service Made Permanent

South Dakota has a County Nurse Law, passed at the last legislature, which gives county commissioners the right to appropriate money for a county nurse and make the work permanent in the county. Several counties have done this and are so pleased with the work the County Nurse is doing that they are now wondering how they got along without her. It is no longer a question of whether a county wants a nurse, but how soon can they get one.

The majority of health work in the schools should be supervised by the public health nurse. Modern Health Crusade work, which is a system of health chores, has been introduced into thousands of elementary schools for the primary purpose of forming good health habits among the children, enlisting children in community service, and controlling preventable diseases.

An eminent physician in a large children's hospital says that the Modern Health Crusade work is the greatest institution for the health of children he has ever witnessed. It not only educates them in proper health living, but forms permanent health habits. "If you want something to last one hundred years, plant a tree. If you want something to last one thousand years, plant a habit in a child, as this habit will be handed down from generation to generation."

In one room in a small city school in the state, 20 per cent of the pupils slept in homes where windows were never opened at night. Many of these children were among the poorest in school work. After following the Crusade work for two weeks, the last child reported to his teacher that his parents permitted him to sleep with his window open. Another child, one of a family of seven, who has been sleeping in a closed attic, by persistent efforts succeeded in getting his father to cut a hole in the room and put in a window.

Another family who had not been getting milk for their children, are reported as using milk daily since finding the children are all undernourished.

Due to physical examinations and health records taken and kept by the superintendent of schools and public health nurse, children become very enthusiastic over all phases of health work, particularly the Crusade work, and are becoming very intelligent in right living.

Nearly all of this work can be supervised by a public health nurse. Health work in the school is not a passing fad. The conservation of the child, like that of world's peace, must be on the mind of all humanitarian people. The child of today must be viewed as the raw material of a new state, the school as the nursery of the nation. To conserve this raw material is as logical a function of the state as to conserve the natural resources of gold, coal, and agriculture.

COORDINATION IN PUBLIC HEALTH NURSING ACTIVITIES

AN AGREEMENT BETWEEN THE AMERICAN RED CROSS, THE NATIONAL TUBERCULOSIS ASSOCIATION, AND THE NATIONAL ORGANIZATION FOR PUBLIC HEALTH NURSING, FOR THE PROMOTION OF PUBLIC HEALTH NURSING.

Foreword.—The Red Cross and the National Tuberculosis Association, through their division and state organizations, being the organizations probably administering the largest number of public health nursing services, and the National Organization for Public Health Nursing, as the voluntary body representing all types of public health nursing, necessarily have many interests and problems in common. Therefore, they seek to supplement each other by utilizing the facilities of each in common as far as possible and by joining forces in undertakings in which it is advantageous to do so. To accomplish this it is necessary that the functions of each organization and the lines of cooperation be clearly defined and future lines of cooperation be, so far as possible, anticipated. These three organizations, through their accredited representatives in conference assembled in Washington, D. C., December 5, 1919, hereby define what each organization considers to be its functions in the field of public health nursing, and enter into an agreement as to methods of performing its functions by means of coordination and cooperation.

The American Red Cross

Definition of Functions.—The functions of the Bureau of Public Health Nursing are:

1. Organization and administration of public health nursing services under the entire or partial direction of Red Cross Chapters through the machinery of the division and state staffs and in cooperation with state departments of health.
2. Education of the Chapters in the principles and practice of public health nursing in order to prepare them to administer such work with the maximum of intelligence and understanding and to the community's greatest advantage.
3. Constant support and guidance of public health nurses in Red Cross service and provision of all educational and informative material needed by them in order to assist them in understanding and meeting rural problems and in organizing and conducting their work to the best advantage.
4. Stimulation of supply of public health nurses through scholarship funds, through financial assistance where necessary for public health courses, and through efforts to interest student nurses and graduate nurses.
5. Research work in the field of practice through analytical studies of various typical and atypical pieces of work for the purpose of determining standard methods of organization, practice, and technic, and for dis-

covering data relating to various problems such as cost of service, variety of personnel required, etc.

6. Conducting demonstrations or experiments in public health nursing by request or as need arises.

The National Tuberculosis Association

Definition of Functions.—The general functions of the National Tuberculosis Association in the public health nursing field are:

1. To act as a clearing house of information about tuberculosis.
2. To suggest policies and programs to its constituent groups.
3. To stimulate the adoption of such methods of teaching tuberculosis, that nurses in training schools shall be made as familiar with this disease as they are with many other diseases which are not so widely distributed.

The National Tuberculosis Association considers that the employment of public health nurses by state and local tuberculosis associations should be for the following purposes:

1. The making of surveys and the demonstration of local needs.
2. Furnishing tuberculosis and public health nursing to communities until such time as the local public authorities are able and willing to assume its support.
3. Staffing of clinics and dispensaries for the diagnosis and treatment of tuberculosis.
4. Follow-up service for the sanatoriums, preventoriums, and open-air schools.
5. Work in the schools with the consent of proper authorities to introduce and supervise the activities of the Modern Health Crusade.
6. As Executive Secretary of state and local associations when such associations so desire.

National Organization for Public Health Nursing

Definition of Functions.—The National Organization seeks, through the following measures, to develop and support standards of public health nursing:

I.—*Educational.*

1. Assisting in the organization and improvement of post-graduate courses in public health nursing.
2. Assisting in the production of more public health nursing teachers through special scholarship fund.
3. Encouraging introduction of instruction in subjects relating to public health nursing and field work into the curricula of qualified training schools.
4. Special institutes for public health nurses already in the field.
5. Circulating package library, advisory service to libraries concerning public health nursing literature, and bibliographies.
6. Public Health Nurse, monthly magazine.

II.—*Recruiting.*

1. Encouraging graduate and student nurses to enter public health nursing.
2. Encouraging high school and college students to enter nursing and to prepare through pre-professional courses. This Organization has proposed that this be continued in cooperation with the other national associations.

III.—*Employment.* Maintenance of a limited employment service which could be developed into a national employment clearing house for public health nurses.

IV.—*Standardization.* Studies of and assistance in establishing standards, methods of organization, administration, publicity, and financial support, records, and reports. This function is naturally the province of all these bodies, cooperatively or individually.

V.—*Legislation.* Creating public opinion in favor of and assisting in the enactment of suitable public health nursing legislation, such as the appropriation of public funds for public health nursing, and the creation of division of public health nursing within state departments of health.

Ways and Means of Cooperation

I.—*Educational.*

1. *Courses.* The Red Cross and the National Tuberculosis Association look to the National Organization for Public Health Nursing to take the lead in matters pertaining to the education of public health nurses. Before granting either financial subsidy or scholarships to a post-graduate course for public health nurses, the Red Cross will require that the course be endorsed by the National Organization for Public Health Nursing. The National Tuberculosis Association will make the same requirement, but will insistently urge through its representative on the Educational Committee of the National Organization for Public Health Nursing that such courses make provision for suitable proportion of teaching of tuberculosis, and is ready to cooperate in establishing standards of teaching for tuberculosis nursing based upon the judgment of the leaders in this field,—medical, nursing, and sociological. It further urges similar consideration for the advice of other specialized health organizations.
2. *Forum.* The Educational Committee of the National Organization for Public Health Nursing will act as a forum for the discussion of all questions pertaining to the education of public health nurses. The Director of the Red Cross Bureau of Public Health Nursing, and the National Tuberculosis Association's Secretary for Nursing, and possibly later representatives of other national public health organizations, will sit on this Committee as members. These organizations will undertake, jointly or separately, but under the general direction of the Educational Committee, to prepare series of monographs on practical methods of conducting various public health nursing activities, and pamphlets on other special subjects as needed.
3. *Institutes.* Believing strongly in the need for annual and widely distributed institutes for public health nurses of considerable experience or training, the Red Cross and the National Tuberculosis Association will join with the National Organization for Public Health Nursing in recommending that such institutes, to cover two weeks or more, be organized and conducted by suitable established agencies within the states, with the assistance of the National Organization for Public Health Nursing, in consultation with these other national bodies. The latter will offer the assistance of their division and state staffs in conducting the institutes and will encourage their local staffs to attend. These three organizations agree that these institutes should be general in character, including tuberculosis, child hygiene, venereal diseases, and other special subjects.

The Red Cross stands ready to suggest subjects and teachers in the rural nursing field, and the National Tuberculosis Association to furnish outlines of lectures and teachers in tuberculosis subjects.

4. *Library.* In view of the fact that the National Organization for Public Health Nursing has a library department with an appropriation for adequate expansion, and has a circulating package library operating through forty-four state library centers, which has been indorsed by the American Library Association, the Red Cross, and the National Tuberculosis Association no endeavor will be made to develop duplicate library facilities but it will be recommended that their field staffs make the fullest possible use of the facilities offered by the National Organization for Public Health Nursing. The latter Organization will undertake to develop its library resources to meet the special needs of these staffs, particularly as their work affects the rural nurses.
5. *Magazines. The Public Health Nurse* has granted a section to the Red Cross Bureau of Public Health Nursing under the editorship of the Director of the Bureau, to be devoted to the activities and development of that Bureau.

The National Tuberculosis Association does not at this time suggest a department in the magazine devoted exclusively to tuberculosis, but suggests that a reasonable amount of space be given to the consideration of tuberculosis nursing and other phases of the tuberculosis movement.

II.—*Recruiting.* The Red Cross hopes to join with the national nursing organizations in a program for recruiting student nurses. The National Tuberculosis Association recognizes that this is distinctly a function of the nursing organizations.

III.—*Employment.* Believing that there are many advantages to be secured through a national clearing house of employment which would serve also as a directory of information, the National Organization for Public Health Nursing will endeavor to accomplish this for public health nurses as a part of the activities of the proposed joint nursing headquarters. It is understood that while all credentials would be obtained by such a clearing house, placements would continue to be made through the various existing agencies.

The Red Cross, because of its great demand on the supply, will appoint its own representatives to the Executive Staff of the Clearing House.

IV.—All three organizations are free to conduct analytical studies of various typical and atypical pieces of machinery for the purpose of determining standard methods of organization, practice, and technic, but will consult each other in planning these studies, in order to avoid duplication and to take advantage to the fullest extent of the facilities and fields each can offer for this purpose.

V.—*Legislation.* The National Organization for Public Health Nursing and the National Tuberculosis Association will seek to create public opinion in favor of, and assist in, the enactment of suitable public health nursing legislation, such as the appropriation of public funds for public health nursing and the creation of divisions of public health nursing within state departments of health. The Red Cross endorses this broad endeavor, but prefers not to take part in efforts involving legislation.

VI.—*Machinery for Coordination.*

1. *Joint Consultation Committee.* The Executive Secretary of the National Organization for Public Health Nursing, the Director of the Bureau of Public Health Nursing of the Red Cross, and the Secretary for Nursing of the National Tuberculosis Association will form a joint consultation committee. This Committee will meet frequently for conference relative to problems and projects confronting or contemplated by any one of the three.
2. Exchange of memoranda regarding new program or change in policy before putting the same into action.
3. State Committees on public health nursing.

The Red Cross Bureau of Public Health Nursing, the National Organization for Public Health Nursing, and National Tuberculosis Association favor and will endeavor to create state committees on public health nursing representing generally the three organizations and the state department of health and other state agencies engaged in or responsible for public health nursing activities. Such a committee will have no administrative responsibility for, but will concern itself with, the advancement of public health nursing in the state through the stimulation of public opinion, through interpretation and advice, and through the promotion of coordination.

It is mutually understood that no changes will be made in the procedure outlined in this agreement without the full consideration of the three participating agencies.

Signed:

American Red Cross,
By F. C. Munroe, general director.
National Tuberculosis Association,
By C. J. Hatfield, managing director.
National Organization for Public Health Nursing,
By Katherine Tucker, president.

FLORENCE NIGHTINGALE TABLEAU

By Gabrielle Elliot, Dramatic Editor of the *Woman's Home Companion.*

(The following tableau, designed to supply a simple dramatic entertainment for training schools wishing to celebrate the centennial of Florence Nightingale's birth, May 12, 1820, have been prepared by the National Organization for Public Health Nursing. Copies of the tableaux, with directions for costuming and staging, as well as suggestions for a reader or expositor, with references to Miss Nightingale's letters and other pertinent material, may be obtained from the Publicity Department, National Organization for Public Health Nursing, 156 Fifth Avenue, New York City, at 20 cents a copy.)

Tableau

1. *Her First Patient.*—"On the downs near Embley." Cap, a collie, lying on the bank. Florence, a girl of sixteen, her petticoat torn to make bandages, is kneeling by the dog binding his broken leg with a splint.

2. *The Nightingale Family Circle.*—Mr. Nightingale reading aloud the *London Times* to Mrs. Nightingale, sewing; the elder sister, Parthenope, drawing. Florence desperately bored and trying to conceal it, also amused. Scene, attractive interior, old fashioned but comfortable. Florence, a young lady now, but marked character.

3. *Her Apprenticeship.*—The Deaconess Home at Kaiserworth, where Florence Nightingale found happiness and her vocation.

Scene: Kitchen or simple almost medieval interior. Freiderike, wife of Fliedner, and with him founder of the Home, at work, but turns towards door through which two probationers—Agnes Jones and Florence Nightingale—enter. They wear simplified deaconess costume and Freiderike, in almost peasant costume, goes to meet them.

4. *Her First Responsibility.*—After much family opposition and not until she was 32 years old, Florence Nightingale made the decisive move which definitely committed

her to her life work. She accepted the position of superintendent of "An Establishment for Gentlewomen during Illness" and moved into the house to the scandal of many friends.

The scene represents a committee meeting—Lady Ellesmere, Lady Canning, Lady Monteagle, Lady Caroline, Murray, and others—stylish, haughty, one or two really interested and sympathetic. (Mrs. Sidney Herbert among the latter.) Miss Nightingale, standing, is bending over a table on which Lady Canning is signing a historic document—one agreeing to take into the institution patients of all denominations—even Catholics and Jews. Miss Nightingale triumphant but amused, ladies varied expressions.

5. *The Call.*—(Three following scenes can be grouped together.)

The Arch-Enemy—Red Tape.

Florence Nightingale, Mrs. Bracebridge, her lieutenant, and a nurse, with the Purveyor, in the stock room of the latter. Florence Nightingale is angry and determined. Mrs. Bracebridge rather amused, nurse frightened at her Chief's defiance of the Purveyor's authority. He is wringing his hands, Miss Nightingale is on her knees before a box, unpacking men's shirts, and handing them up to Mrs. Bracebridge.

6. *The Endless Letters Home.*—Miss Nightingale's tiny room in the hospital at Scutari. At a table piled high with documents, letters, etc., she is writing by a sputtering lamp. Mrs. Bracebridge, worn out, is sleeping on a couch. A nurse, ill, is in a bed near the table, another nurse bends anxiously over her. Two near the door confer, watching Miss Nightingale, who writes rapidly, a frown of concentration on her forehead and an official looking document propped up in front of her. The room is badly lighted, over-crowded, yet she is oblivious to everything about her in the ardor of her work.

7. *The Lady of the Lamp.*—The wards of the hospital at Scutari. Beds, uneven in length, with various coverings, so near that one could hardly wedge between them; men, half-sitting and lying prone, attitudes expressing pain or unconsciousness, Florence Nightingale, her lamp held high, bends over one man gently, arranging the covers or feeling his brow. From the lamp's rays her shadow should fall on the bed of another, who kisses it as it touches his pillow.

8. *Home Again—"The Reform Cabinet."*—Miss Nightingale's room, pleasant but business-like. Blue books, documents, letters around her. She is seated in a semi-invalid chair, but with an open book, over which she bends with eager interest. Sir Sidney Herbert, her strongest ally, stands beside her, equally interested in the book. A few men and women, examining other books, express delight and pride in Miss Nightingale. The book is the first printing of the Report of the Royal Commission, appointed after Miss Nightingale's repeated efforts to inquire into the health of the army. Attitudes of congratulation, on the part of all but Sir Sidney and Miss Nightingale.

Reader: Cook, Vol. 1, 274 ff. Choose passages indicating Miss Nightingale's continued vitality and scorn of red-tape, also Sir Sidney Herbert's efforts in her behalf. You will have to give the atmosphere of the enormous accomplishment really achieved from a sickroom.

9. *The Council Room to Which Queens Came.*—Florence Nightingale, propped up in bed, endless books, reports, etc., around her. See pictures of her in her room. The Crown Princess of Prussia, her hat and coat thrown aside, kneels by the bed, on the side of the audience, with a huge portfolio of architect's blue prints, from which she draws one and submits it eagerly but deferentially to Miss Nightingale's amused approval.

10. *Unsought Honors, 1907.*—The presentation, on November 20, 1907, of the Order of Merit, bestowed by King Edward, Miss Nightingale being the first woman to receive it. At the time she was nearly 90 years old, and memory, sight, and mental vigor had sadly failed. Surrounded by nurses and friends, the medal is presented by Sir Douglas Dawson on the King's behalf, while Miss Nightingale, murmuring vaguely "too kind, too kind," recognizes that some formal honor is being presented.

The curtain may fall on this last scene and be followed by a reading of Miss Nightingale's stirring call for nurses, in her own words, leaving the audience to make the connection with the need of the present day.

FLORENCE NIGHTINGALE PLAY

It is apparent already that the hundredth anniversary of the birth of Florence Nightingale, which occurs on the 12th of next May, will be widely celebrated. In many of the larger cities plans are under way for the holding of public meetings and appropriate ceremonies. One of the most interesting features of the celebration is the $500 prize, offered by the Central Council for Nursing Education, for the best three-act play by an American author based on incidents in the life of Florence Nightingale. The competition is especially designed to encourage aspiring playwrights in the colleges and to stimulate interest in the nursing profession. In view of the difficulties which the Hospital Training Schools are experiencing in securing sufficient numbers of desirable applicants, this competition should be extremely serviceable. All manuscripts must reach the Nightingale Centennial Committee, National Organization for Public Health Nursing, 156 Fifth Avenue, New York City, before August 1, when the competition closes. Another interesting contribution of the Centennial Committee is the preparation of the Nightingale tableau, a condensed version of which is printed in the preceding article.

TRAINING NURSES FOR INDUSTRY

The New York University School of Commerce, Accounts, and Finance is offering a course the second semester (February to June, 1920) in Standardization of Nursing Service in Industry. The course is especially arranged for industrial nurses, welfare workers, and those who contemplate entering the field of industrial welfare work.

Students enrolled in the course will be given an opportunity to make special investigations of nursing problems in large industrial plants, with particular reference to administration and organization.

Special consideration will be given such topics as: (1) Duties and responsibilities of the nurse in small and large industries; (2) Methods of teaching the worker and his family how to keep well; (3) Most approved methods required for follow-up health service in the plant; (4) Relation of the nurse to the industrial community; (5) Home nursing and personal hygiene; (6) Reducing labor turnover through health measures; and (7) Amount of hospital care available for the worker.

The fee for the course of one term is $12, plus a university fee, payable in advance. The enrollment will be limited, and applicants must be approved by the director of the department, Prof. Galloway, or by the instructor, Miss Elizabeth H. Bohn.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

APPLIED ANATOMY AND KINESIOLOGY. The Mechanism of Muscular Movement. By Walter Pardon Bowen, M.S., professor of physical education, Michigan State Normal College, Ypsilanti, Mich.*

A rather interesting volume of three hundred and thirty-four pages. The first thirty-one pages describe muscular structure and action, and the methods of studying and measuring such action. Pages 32 to 39 show very well the various types of levers that the bones in the body represent. Pages 40 to 58, present concisely the manner in which the nervous system controls the muscular. The foregoing constitutes Part I. Parts II, III, and IV describe the muscles of the limbs and trunk and their actions, also the means used in determining what certain muscles do. Part V takes up different exercises and occupations with the muscles or groups of muscles used in performing them. The book should prove very useful to all those interested in physical development and its mechanics.

AIR, WATER AND FOOD. From a Sanitary Standpoint. By Alpheus G. Woodman and John F. Norton.†

Although the book has had its chief use as a college and technical school text, and although it had been rewritten since the death of Mrs. Ellen H. Richards, the original co-author with Professor Woodman, it still retains a great deal of its original "missionary" character.

It is the hope of the authors that a book of the character they have offered will contribute to a better education of laymen in the chemistry of sanitation and, as a result of it, enlightened public opinion will accelerate the progress of sanitation. "The day is not far distant when a city will be held as responsible for the purity of the air in its schoolhouses, the cleanliness of the water in its reservoirs, and the reliability of the food sold in its markets as it now is for the condition of its streets and bridges" . . . , and "when the competency of the food purveyor will have as much weight with intelligent patrons as the scholarly reputation of any member of the faculty." Whether the authors are unduly optimistic or not, this, however, can be said: that the spirit with which the book is permeated gives, no doubt, to the student the desired scientific and civic impetus.

The purpose and "mission" of the book are best characterized by two sentences from the first chapter:

"So long as chemists are employed by manufacturing concerns in making adulterated and fraudulent foodstuffs, so long must other chemists be employed in protecting the people until the public in general becomes wiser. A part of the common knowledge of the race should be the essentials of healthful living, in order that the full measure of human progress may be enjoyed."

The book contains a great deal of valuable and well compiled information.

In view of the important recent studies in ventilation made since the book had been written, and also in view of the instructive experiences concerning food which can be derived from the war conditions, it is desirable that the book be again revised and brought up to date.

SURGICAL APPLIED ANATOMY. By Sir Frederick Treves, Bart., G.C.V.O., C.B., LL.D., F.R.C., Eng.; Sergeant Surgeon to H.M. the King; consulting surgeon to the London Hospital; late lecturer on anatomy at the London Hospital. Revised by Arthur Keith, M.D., LL.D., Aber., F.R.C.S., Eng.; F.R.S., Hunterian Professor and Conservator of the Museum, Royal College of Surgeons of England; formerly lecturer on and senior demonstrator of anatomy at the London Hospital; examiner in the Universities of Aberdeen, Cambridge, etc.; and W. Colin Mackenzie, M.D., Melb., F.R.C.S., Edin., F.R.S.E.; member of Council of the Anatomical Society of Great Britain and Ireland; formerly lecturer on applied anatomy, University of Melbourne.‡

In presenting the new (seventh) edition of Treves' Surgical Applied Anatomy, Keith and Mackenzie have done a great service for the profession. This little treatise is too good to be allowed to grow old and senile, and we are pleased to note its rejuvenation.

Like the former editions, the book is clear, concise, and remarkably detailed, covering the field of surgical anatomy.

To quote from the preface of the seventh edition: "Although many additions have been made to and minor alterations effected in the present edition, this book still retains the spirit, form, and size given to it by its distinguished author."

A LABRADOR DOCTOR. The Autobiography of Wilfred Thomason Grenfell, M.D. (OXON), C.M.G.§

Anyone who likes to read tales of good deeds well done will have a few pleasant hours with this book. Medical men in particular will feel a glow of virtuous pride that Grenfell was a doctor and that as a doctor he was able to accomplish so much. Readers of Galsworthy's "Saint's Progress" will find a pleasant comparison between the inactive theologian of Galsworthy, who has been left behind by the progressive thought and radical actions which were brought to a focus by the war. In comparison Grenfell's life stands out as a living monument to active carrying of the Word of God to men in the wilderness.

The early life of Grenfell, which is so interestingly told as to sound like pages from a modern English novel, lays bare the disadvantages as well as the advantages of primary education in England. Some of his chapters might be labeled as exhibits to prove Wells' ideas on English education. But the personal contact with big men, the association with Sir Frederick Treves, the row-

The busier one Is—the more one Needs the perfect relaxation that only good sound sleep can give

Physicians, Public Health Officials, and Industrial Welfare Workers know the importance and money value of good sound sleep.

Their work in keeping people well, keeping them physically fit, mentally and physically efficient, affords countless opportunities for determining the health-building advantages of sound, restful sleep.

It is a big temptation these days, with so much to be done, for one to cut down on their amount of sleep; but the fact remains that the busier one *is*, the more one *needs* the perfect relaxation that only good, sound sleep can give.

Most people probably need *more sleep*; certainly they need *better sleep*. And this means better beds; quiet, restful beds; beds that do not squeak, groan and rattle with every turn of the occupant.

Thousands of people declare that they never realized how deep and sound sleep can be, until they discarded wooden beds and ordinary metal beds for a Simmons Bed—noiseless, restful, sleep inviting.

Simmons Beds are noiseless; they are supremely restful and comfortable. They are strongest, where ordinary beds are weakest, at the corner locks. They stand firm, without a squeak, rattle, or suspicion of unsteadiness. Furthermore they are absolutely sanitary.

Is it any wonder, then, that Simmons Beds are the choice of up-to-date Hotels, Hospitals, Schools and Industrial Dormitories, just as they are the choice in thousands upon thousands of *homes?*

Simmons Beds are made entirely of metal—splendidly finished. They are produced in so wide a variety of styles as to enable anybody, no matter how much or little they wish to pay, to own and sleep in a *genuine* Simmons Bed.

Our complete catalog of Simmons Beds and Sleeping Equipment will be mailed promptly upon request. Address:

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 268.)

ing club, the missionary work in the slums of London, have a personal touch which adds charm and dignity to every page of the book. The descriptions of life in Labrador, of the people, go a long way towards dissipating the chill of disapproval one usually feels at the mere mention of Labrador.

The reviewer could continue commenting on the good points of this book almost indefinitely. Instead, however, he will put it away carefully along side of his Pasteur, his Trudeau, on the biographical shelf to which he goes when he needs a word of cheer or a bit of encouragement.

PRACTICAL DIETETICS WITH REFERENCE TO DIET IN HEALTH AND DISEASE. By Alida Frances Pattee, graduate, department of household arts, State Normal School, Framingham, Mass.; late instructor in dietetics, Bellevue Training School for Nurses, Bellevue Hospital, New York City; former instructor at Mount Sinai, Hahnemann, and the Flower Hospital Training Schools for Nurses, New York City; Lakeside, St. Mary's Trinity, and Wisconsin Training Schools for Nurses, Milwaukee, Wis.; St. Joseph's Hospital, Chicago, Ill.; St. Vincent de Paul Hospital, Brockville, Ont.*

Any book which has passed through twelve editions in sixteen years must be a good book. This book is a good book and is deserving of the cordial reception always given previous editions.

MENTALLY DEFICIENT CHILDREN, Their Treatment and Training. By G. E. Shuttleworth, B.A., M.D.; Fellow of Kings College, London; Honorable Consulting Physician, formerly medical superintendent, Royal Albert Institution, Lancaster, for the Feeble-Minded of the Northern Counties; and W. A. Potts, M.A., M.D., medical officer of the Birmingham Committee for the Care of the Mentally Deficient, etc.†

The authors have succeeded in presenting a full discussion of mentally deficient children in a pocket size booklet of 284 pages. The pathology, symptomatology, and bibliography are up to the minute. The plates taken from the authors' own cases add a great deal to the completeness of the book.

Chapters two and three are a little too local, the material in these chapters consisting of reports of mental deficiency acts and investigations in England, including many local names. Chapter one, however, shows that while the authors are inclined to lay most stress on work done in England, they have not forgotten to give credit to American and French institutions. Indeed, it is gratifying to read of the good work done by various American counties and states towards the improvement of the mental defect.

The booklet reads well and can be used not only by physicians, but also by nurses and school teachers.

A TREATISE ON ORTHOPAEDIC SURGERY. By Royal Whitman, M.D., M.R.C.S., Eng., F.A.C.S.‡

Whitman's Orthopedic Surgery, in its sixth edition, has been subjected to a revision, bringing it into accord with the latest knowledge of the subject. It contains 900 pages, printed in large type on good paper and abundantly illustrated. Some of the old statistics and references might have been eliminated, being of little value; and many of the subjects, too briefly described, should have been amplified as to details. The final chapter devoted

SOFOS

SOFOS is a product of the research laboratories of the General Chemical Company—one of the world's leading scientific organizations—a strictly American institution.

SOFOS—An Entirely New Preparation

The therapeutic value of sodium phosphate was established years ago—is admitted beyond question today. But, the best, which means the most efficient form in which to administer sodium phosphate, is a matter of present day performance, as supplied by

SOFOS

a preparation of monosodium phosphate NaH_2PO_4 and sodium bicarbonate $NaHCO_3$.

Its freedom from citric or tartaric acid makes it available in all cases where sodium phosphate is advisable.

SOFOS effervesces in water and forms di-sodium phosphate.

One part of SOFOS contains almost twice as much sodium phosphate as the U.S.P. salt.

The pleasant taste and prompt laxative action of SOFOS make it superior. The absence of tartrates, citrates, or unsatisfied salts, assures efficient action, and insures against "nagging" irritation or subsequent costiveness.

SOFOS is particularly serviceable in children, old people, and in debilitated or adynamic states.

SOFOS has been accepted by the Council on Pharmacy and Chemistry of the A.M.A. for inclusion in New and Non-official Remedies. Ask your pharmacist for SOFOS. If he hasn't any, notify us.

BOOKS OF THE MONTH

(Continued from page 22.)

to military orthopedics and the early development of practical reconstruction presents the most "notable change" in the treatise. Altogether, the present edition is the most reliable, definite, and concrete source of information we possess in the form of a textbook on orthopedic surgery, valuable alike to all who are interested.

THE OPERATIONS OF OBSTETRICS. Embracing the Surgical Procedures and Management of the More Serious Complications. By Frederick Elmer Leavitt, M.D., formerly assistant professor of obstetrics and gynecology, University of Minnesota; obstetrician to the City and County Hospital, the St. Paul Hospital, the Bethesda Hospital, etc., St. Paul, Minn.*

Careful perusal of this latest contribution to obstetric literature leaves the reader with some very definite impressions. The book is well written, splendidly illustrated, and attractively gotten up by the publishers. The problem of operative obstetrics is presented completely and clearly, though with a tinge of conservatism, which, after all, befits a work designed for students and practitioners. The writer uses to good advantage, judiciously selected quotations from literature, especially statistics, but employs less advantageously rather lengthy case reports. One cannot entirely suppress the feeling that here and there the space taken up by such a case illustration, should rather have been used for a more detailed discussion, *e. g.*, of the exact indications for justifiable premature termination of pregnancy in various complicating diseases. This question, one of eminent practical importance, undoubtedly in this volume is not considered in a form that could offer the practitioner definite advice.

It would seem desirable in a future edition to devote also more space to a description of the various methods of extra-peritoneal Cesarean section, to mention direct blood transfusion in the treatment of severe hemorrhages, to discuss the particular advantages of spinal anesthesia in certain cases, and to emphasize the particular danger of chloroform in the severer types of toxemia; but, as stated in the beginning of this review, as a whole, this volume most assuredly is a very interesting and competent exposé of modern teaching of operative obstetrics.

ORTHOPEDIC AND RECONSTRUCTION SURGERY, Industrial and Civilian. By Fred H. Albee, A.B., M.D., Sc.D., F.A.C.S., Lieutenant Colonel, M.C., U.S.A.; professor and director of Department of Orthopedic Surgery, New York Post-Graduate Medical School and University of Vermont; chairman, Rehabilitation Commission of the State of New Jersey; member of Advisory Orthopedic Council to the Surgeon General, etc.†

In the preface the author states that the diversity of diseases, injuries, etc., treated is much greater than ten years ago and the publication, while in no way detracting from conservative methods, aims to place before the profession in a practical manner newer procedures. The introduction is a generalized discussion of a few of the principles of orthopedic surgery. Then, proceeding to the text proper, in Chapter I, we have a general discussion of tuberculosis of bones, the etiology, pathology, and treatment. Chapters II to VIII, inclusive, deal with tuberculosis of particular bones and joints, one chapter being given to the fundamental principles of the bone graft. Chapters IX, X, XI dispose of focal infection, acute and chronic infections of bones and joints. Chapter XII,

EASY TO READ, TO THE POINT, AND PRACTICAL

A Reliable Reconstructive Agent

In cases of debility, weakness and anemia following influenza, the Triple Arsenates with Nuclein (Abbott) is your best tonic preparation. This excellent reconstruction combines the arsenates of iron, quinine, and strychnine with nuclein. Throw away your antiquated "I. Q. S." with its useless water, and worse than useless alcohol, and pin your faith to this preparation. Use the corner coupon for a trial order of 500 tablets at $0.94 net. You will get results.

For Your Convenience

Your druggist will stock, for your convenience in prescribing such popular items as Calcidin, Chlorazene, Sodoxylin, Abbott's Saline Laxative, Salithia, Barbital, Cinchophen, and Aromatic Chlorazene Powder.

Convenient branch offices of The Abbott Laboratories are also located in New York City, San Francisco, Los Angeles, Seattle and Toronto.

Make use of these trade channels and supply points for prompt service.

FOLLOWING THE "FLU"

Triple Arsenates with Nuclein is the best reconstructive agent you can use.

Eating Should Be An Enjoyable Function

In the restoration—and even in the *maintenance* — of physical well-being, no adjustment of the diet can be regarded as satisfactory which leaves out of consideration the factor of food flavor.

Physicians and dietitians appreciate that, in nearly all cases, food that is pleasing to the taste is more easily digested and assimilated than that eaten with less relish.

SAUER'S

PURE FLAVORING EXTRACTS

—Since 1887 flavoring the food of millions.

recommend themselves to the patient, the physician and the dietitian through their contribution of zest to foods and drinks which might not otherwise be so tempting.

Sauer's Extracts are made from the choicest materials obtainable. Every possible care is taken in their manufacture.

Specify Sauer's for Purity, Strength and Fine Flavor.

Sauer's is the largest selling brand in the United States.

Further particulars sent free.

The C. F. Sauer Company

Richmond, Virginia

BOOKS OF THE MONTH

(Continued from page 24.)

on traumatic affections of the spine, is rather interesting. Scoliosis is presented in the usual textbook way. Ninety-one pages are used to present malunited fractures of the long bones, a few other fractures and their treatment by the author's method of bone grafting. Infantile paralysis is properly given a large space and is rather thoroughly done. Neoplasms are mentioned in passing, as it were. Military and industrial reconstruction is given ninety-seven pages at the last of the book. References are profuse at the end of each chapter. The author rather emphasizes his methods of procedure for the treatment of various deformities and injuries. The pages between 272-289 are considerably mixed. Reviewing the volume has on the whole been a pleasure.

SURGERY AND DISEASES OF THE MOUTH AND JAWS. A Practical Treatise on the Surgery and Diseases of the Mouth and Allied Structures. By Vilray Papin Blair, A.M., M.D., F.A.C.S., professor of oral surgery in the Washington University Dental School, and associate in surgery in the Washington University Medical School.*

This volume is a very excellent contribution to medical literature. In it the author treats a field which is not generally covered in a thorough manner by other than the large systems on surgery. The author has spent a great deal of time and effort on his anatomical plates and descriptions, which alone would recommend the volume to the student. It is also written in a manner that is equally valuable to the surgical specialist, the general surgeon, and the dental surgeon.

In some of the chapters detail and principles are given such an important part that one must consider the author's preface, that these chapters are included for the benefit of his dental students. The author incorporates many excellent ideas and conclusions from extensive experience in plastic surgery, gained while in charge of the subsection of plastic and oral surgery in the Army.

The chapters on cleft palate are well written and accompanied by good illustrations. The author's modification of the Brophy technic for restoration of the alveolar arch in cases with complete separation of the maxillae has been repeatedly observed by the reviewer, with good results when performed early.

Cancer of the tongue is perhaps the best treated subject of the whole book. The industrial surgeon will find a great deal of valuable information on the treatment of jaw fractures.

The statistics of the British Army would encourage the use of the warm ether vaporizer as advocated by the author; however, the experience of Farr would conclude the author's armamentarium for local anesthesia and methods of preparation of anesthetic solutions to be inadequate for major surgery. His experience also does not confirm the author's statement that it is necessary to wait fifteen minutes for infiltration anesthesia. Farr has removed the tongue, made complete dissections of the neck, resected both maxillae, and on no occasion has he been compelled to wait at all after the completion of the infiltration. He condemns the preliminary outlining of the flap with a sharp instrument on unanesthetized skin and has greatly improved the author's technic of producing secondary wheals by making all but the primary wheal painlessly from beneath. Repeated small hurts, even pricks from the finest hypodermic needles, cause a nervous patient to lose confidence.

(Continued on Adv. Page 28.)

Bowel regulation through diet

HERE is a new all-bran food, entirely *different* from any bran you've ever seen. It doesn't resemble in any way the dry, tasteless, ordinary bran; it has a different appearance and different flavor.

An ideal food for the counteraction of constipation and for positive regulation of the intestinal tract.

And because its delicate flavor appeals to the patient there's no difficulty in having your prescription carried out.

Kellogg's KRUMBLED BRAN

Thoroughly cooked, specially "Krumbled" by the exclusive Kellogg method and ready to serve. Makes excellent bread, muffins, porridge, puddings, etc. Every package comes to you protected by the Kellogg "waxtite" wrapper and bearing a variety of tempting recipes. Genuine Kellogg's Krumbled Bran is guaranteed by this signature— *W. K. Kellogg*

Electrically Lighted Surgical Instruments

The Sign of Service

E. S. I. Co.

Ours is a name of accomplishment in the cause of diagnosis. In the beginning an electrically lighted surgical instrument is made to embody the ideas of a distinguished physician or surgeon. Each accomplishment by the light of this instrument is a tribute to his skill and its efficiency, opening the way to greater gains for diagnosis and to suggestions for betterments in instrument construction.

Building upon the ideas and from the suggestions of these physicians and surgeons, admittedly great in the respective branches of their exacting profession, is the story of "E. S. I. Co.," from the origination of electrically lighted surgical instruments up to the indispensable service they render today.

Origination begets imitation. Be sure of our name.

BOOKS OF THE MONTH

(Continued from Page 26.)

A good index and bibliography should help to make this book popular as both a text and a handy work of reference.

THE DISEASES OF INFANTS AND CHILDREN. By J. P. Crozer Griffith, M.D., Ph.D., professor of pediatrics in the University of Pennsylvania, Philadelphia; physician to the Children's Hospital of Philadelphia, and to the Children's Medical Ward of the University Hospital; consulting physician to St. Christopher's Hospital for Children, Philadelphia; corresponding member of the Société de Pédiatrie de Paris.*

The task of the reviewer of pediatric textbooks has not been a particularly happy one for the past several years. Again and again he has waded through unnecessary and uncalled-for volumes issued at the importunities of the publisher of medical textbooks in search of that *rara avis* —a "good seller." Some have been half-baked manuals, others unripe textbooks, and a few ungrammatical translations. And so it had reached a point that a new volume on pediatrics was opened with reluctance. Only a few months ago while discussing the subject with one of our well-known publishers, the reviewer advanced the opinion that the time had passed when any one author could write a general book on pediatrics that was worth the paper used for its printing, especially in these days of expensive publication.

The reviewer has since seen the publisher and retracted. The unexpected has happened, and for the first time in many, many months the reviewer has been reading a new book with both pleasure and profit. In his opinion and judgment the new two-volume textbook by Dr. Griffith is the first substantial addition to American pediatric textbooks since Dr. Holt published the first edition of his well-known work in 1897.

One cannot discuss in detail over fifteen hundred pages. Here and there one quite naturally finds details with which he disagrees, but these are so over-balanced by the completeness of the work, the sense of proportion, the saneness of viewpoint, and the openness of judgment, that such details sink into insignificance. Above all one senses throughout the work the vast personal experience of the author—the harvest of his forty years of practice and teaching—which he communicates in an unusual degree to the reader.

Dr. Griffith has made no claim to be a chemist or a student of metabolism in the modern sense—the present fashionable mode of entering pediatrics—but his discussion of this subject shows a thorough knowledge and critical sense of the essentials as proved in this field. Perhaps most criticism will be directed—and this by the younger generation—to the pages entitled, "General Principles of Substitute Feeding," and particularly to the subhead under this, "The Calculation of Milk Formulae." It is here that the reviewer differs most radically from the teachings of Dr. Griffith, although it must be admitted that the methods advocated by the author are the ones that he found useful and practical and to have given good results over years of experience. It would add to the value of the whole if only a short paragraph were added on the details of simple milk dilution. The chapter on drugs and treatment, infant foods, hygiene, and the other details regarding infancy are excellent.

It is, however, the remainder of the textbook which is of most value to the physician, both practitioner and specialist. Dr. Griffith has not simply revamped known facts

(Continued on Adv. Page 30.)

HAY-FEVER
Can be Prevented

CLINICAL results covering more than 12,000 cases, attest the value of **Pollen Antigen.**[1] During the past five years, from 1915 to 1919 inclusive, **Pollen Antigen** has afforded relief from hay-fever by conferring an average protection of 82.7%.

THE treatment with **Pollen Antigen** should be started six weeks before the date of the usual onset of hay-fever. Even in those not protected, the symptoms are usually rendered mild and the attack cut short.

POLLEN Antigen is now universally used for hay-fever because:

1. Contains all the antigenic properties of pollen grains.
2. Will not deteriorate.
3. Standardized by complement fixation.
4. May be used without preliminary diagnostic tests.
5. Gives uniformly consistent results each year.

Industrial physicians and health officials will be especially interested this year in Pollen Antigen because through its use absenteeism and lowered production due to Hay-Fever can be prevented.

REQUESTS for further information are invited.

5 Cents

will serve five liberal dishes of Quaker Oats. That's the cost at this writing of a single egg.

60 Cents

is the cost at this writing of five lamb chops. A chop costs 12 times a dish of Quaker Oats.

Cost per 1000 Calories

Quaker Oats yield 1810 calories per pound. The cost is 5½ cents per 1000 calories.

Meats, on the average, cost about 45c per 1000 calories, fish about 50c, and eggs about 70c.

Yet the oat is almost the ideal food in balance and completeness. Most other foods cannot compare with it.

These are facts to spread, we argue, in these high cost days.

Quaker Oats

A superior grade, flaked from queen grains only—just the rich, plump, flavory oats. We get but ten pounds from a bushel. This grade means extra flavor without extra price.

BOOKS OF THE MONTH

(Continued from Page 28.)

in regard to disease as it manifests itself in children, but has combined his own personal experience with what is perhaps the best review of the essential pediatric literature of the past twenty years. So far we have not read over a single subject without the feeling that we have gained something. The book gives evidence of years of preparation and writing with constant revision bringing it up to date. The publishers have joined with Dr. Griffith in issuing a readable page replete with original illustrations and have added much to the value of the work by including references. It can be said without the slightest exaggeration that Dr. Griffith has written a work of real value and one destined to occupy a permanent place on many shelves. B. S. V.

PRINCIPLES OF SURGICAL NURSING. A Guide to Modern Surgical Technic. By Frederick C. Warnhuis, M.D., F.A.C.S., visiting surgeon, Butterworth Hospital, Grand Rapids, Mich.; chief surgeon. Pere Marquette Railway; secretary of the Michigan State Medical Society; editor of the Journal Michigan State Medical Society, member of the Michigan State Board of Registration in Medicine.*

In a short, clear, concise manner, Warnhuis presents the guiding principles of surgical nursing technic of today.

In excellently illustrated chapters, the author takes up the preparation of the patient for operation; the preparation of the operating room in a hospital or in a private home; the duties of the nurse during operation; the usual care of the patient during the first twenty-four hours after operation; the post-operative emergencies that might arise; and many other things the surgical nurse ought to know, such as the methods of keeping charts, of preparing the usual surgical materials, such as gauze, drains, pads, etc.; of making poultices, and the common antiseptic solutions, are dealt with in detail.

The book will be extremely useful, not only to the nurse who expects to take care of surgical cases, or to the teacher in a training school, but also to the country practitioner who, not having the advantages of a hospital, must operate in homes and usually is too busy to be able to attend to the details himself.

A TEXTBOOK OF CHEMISTRY FOR NURSES. By Fredus N. Peters, A.M., Ph.D. Author of "Experimental Chemistry," "Laboratory Experiments," "Modern Chemistry," etc.; formerly professor of chemistry and director of laboratories, Kansas City College of Pharmacy; professor organic chemistry, Hahnemann Medical College; director of laboratories and professor of chemistry and metallurgy, Kansas City Dental College; head of science department, Kansas City Central High School.†

There is only one way to teach chemistry properly, whether to nurses or any other type of students, and that is by beginning systematically with inorganic chemistry and supplementing this by a thorough laboratory course. After the fundamentals of the science have been assimilated, the more intricate subject of organic chemistry may be tackled.

The author has attempted the difficult task of presenting, in one compact volume, the essentials of both organic and inorganic chemistry in such a way that the student might get the maximum in the small space of time allotted to this subject in the nurses' curriculum.

The book is very practical and popularly written.

FOR DIET CONTROL IN INFANT FEEDING

The choice of these dependable products affords the physician convenient means of selecting food mixtures suited to the individual requirements of individual cases.

MEAD'S DEXTRI-MALTOSE NO. 1

(With Sodium Chloride 2%)

For general use in infant feeding. Especially indicated in infants recovering from diarrhoea, infants with feeble powers of digestion who have tendencies to diarrhoea. Valuable as an addition to Protein Milk.

MEAD'S DRY MALT SOUP STOCK

For difficult feeding cases. Indicated in marasmus, weight disturbance (failure to gain), infants afflicted with recurrent diarrhoea from intestinal indigestion, and those cases occasionally met which do not do well on milk, water and sugar mixtures.

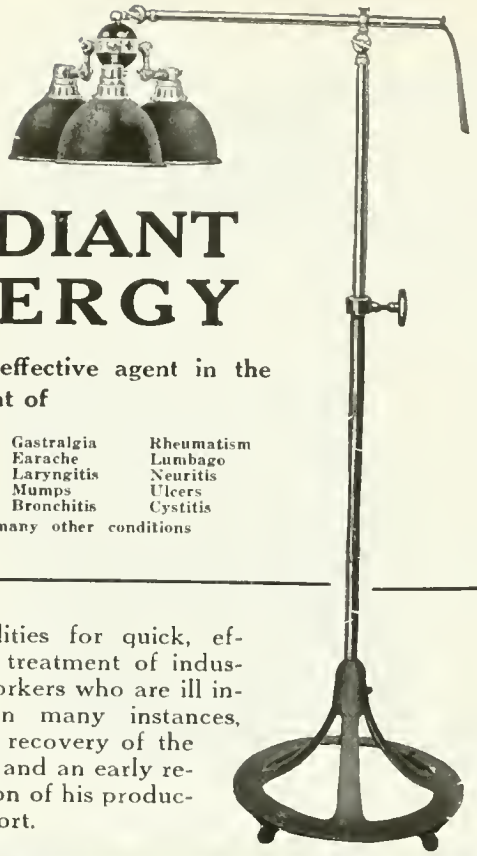
MEAD'S DEXTRI-MALTOSE NO. 3

(With Potassium Carbonate 2%)

For use in constipation, when boiled feedings are used, or where the addition of potassium to the infant's diet is indicated.

Full information regarding these products furnished on request.

MEAD JOHNSON & CO. **Evansville, Ind.**



RADIANT ENERGY

—a most effective agent in the treatment of

Neuralgia	Gastralgia	Rheumatism
Arthritis	Earache	Lumbago
Dermatitis	Laryngitis	Neuritis
Dismenurrhea	Mumps	Ulcers
Shingles	Bronchitis	Cystitis

and many other conditions

Facilities for quick, effective treatment of industrial workers who are ill insure, in many instances, speedy recovery of the patient and an early resumption of his productive effort.

Thermolite
LIGHT AND HEAT INFUSER

Delivers Radiant Light and Heat in PARALLEL Rays

Because the rays are **parallel**, they bring quick relief from pain, reduce inflammation, and promote healing.

ThermoLite is supplied in two forms—the **Triplex** for hospital clinics and office use, and **Simpex** (single lamp with or without stand) for home use.

H. G. McFaddin & Co.
39 Warren St., New York City

THE NATIONAL CONFERENCE OF JEWISH CHARITIES

The annual meeting of the National Conference of Jewish Charities which was scheduled to meet in New Orleans in April, jointly with the National Conference of Social Work. has been postponed until a later date, the meeting to take place somewhere in the East.

NATIONAL TUBERCULOSIS ASSOCIATION MEETS

The annual meeting of this organization for 1920 will be held at St. Louis April 22 to 24, with headquarters at the Statler Hotel. The dates immediately precede the meeting of the American Medical Association at New Orleans and immediately follow the meeting of the National Conference of Social Work at New Orleans, so that members attending either of the latter conferences can stop at St. Louis on their way to or from New Orleans.

AMERICAN MEDICAL ASSOCIATION MEETING

The annual meeting of the American Medical Association will be held April 26-30, 1920, in New Orleans. The greatly broadened and intensified public interest in medical matters this year has evolved issues of vital interest to the medical profession. The sectional programs are of unusual value. A large attendance at this meeting and a general participation in its deliberations are urged.

RED CROSS PEACE PLAN

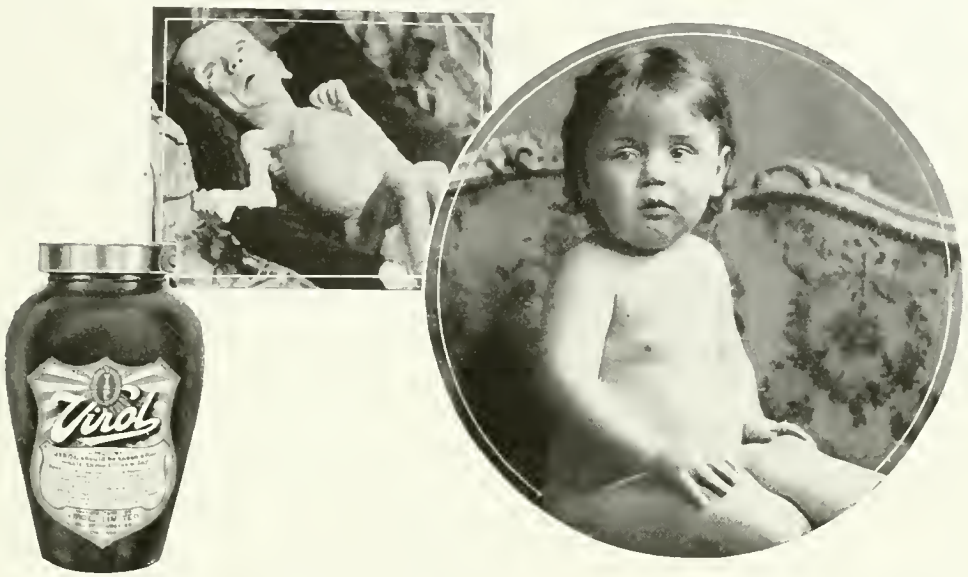
The meeting of the General Council of the League of Red Cross Societies convened at Geneva, Switzerland, on March 2. The object of the conference is the consideration of a program by which the national Red Cross societies may extend their activities in peace times by carrying out a universal campaign against disease. The American delegates to the Conference are Willoughby G. Walling, Chicago; Otis H. Cutler, New York; Mrs. William K. Draper, New York; Samuel Mather, Cleveland; and Eliot Wadsworth, Boston. The delegation will be accompanied by Henry P. Davidson, chairman of the Board of Governors of the League.

APPROPRIATION TO COMBAT INFLUENZA

The Senate has passed a joint resolution appropriating $500,000 to be used by the Public Health Service in combating influenza. The resolution directs the Public Health Service to investigate influenza and allied diseases in order to discover their causes and prevent their spread. It requires allotment of money to universities, colleges, and other research institutions for scientific investigation. The Public Health Service is accorded the privilege of making selection of such institutions. A forceful debate occurred in the Senate prior to the adoption of the resolution, Senator King of Utah opposing the resolution and objecting to the "constant encroachments of the Public Health Service organization." He said: "We will soon have the United States furnishing doctors, nurses, and hospitals for all the people, with the result of hundreds of millions of dollars being taken annually from the people." The resolution originally provided for an expenditure of $1,000,000. Senator France in charge of the resolution acquiesced in the amendment, reducing the amount to $500,000. The resolution now goes to the House of Representatives.

The nutrient value of VIROL illustrated in a series of cases, particulars of which have been supplied by medical men.

CASE No. 4



Virol is a valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars: 50c, $1.00 and $2.00.

Liberal samples and interesting literature sent to physicians on request.

MARASMUS—VIROL is indicated in *all* conditions requiring special nutrition, such as marasmus, rickets, measles, whooping cough, infantile diarrhoea, etc.

In the case of babies not thriving on natural feeding, remarkably good results are achieved by the administration of Virol to the nursing mother. Small quantities of Virol may also be given to the baby between feedings.

Baby Povall wasted away until at six months old he only weighed 6 lbs. 8 ozs. In this terrible condition VIROL was given, and an immediate improvement took place. After four months' feeding on VIROL he took a prize at a Baby Show. Note the splendid condition of this 31-1/2 lb. baby.

Physical Conditioning

So many patients, especially women, lack the initiative to follow general advice regarding exercises, dietary, and personal hygiene. Physicians acquainted with my work are constantly referring these cases to me for physical and mental "conditioning."

A woman can often inspire her sex *to be* and *to do* and *hold her to this inspiration* by regular correspondence as men cannot.

Every pupil's requirements are studied individually, and each is directed according to her needs and her strength.

This cooperative work with the medical profession is giving results highly gratifying to both physicians and patients.

I shall be glad to assist you with patients who need conditioning through exercise, diet, breathing, correct poise, relaxation, reduction of flesh, or building of flesh.

Susanna Cocroft

624 Michigan Boulevard Chicago

HARVARD ENGINEER IN BUREAU OF HYGIENE

Professor George C. Whipple, of Harvard University, has been appointed director of the Division of Sanitation, in the Bureau of Hygiene, of the League of Red Cross Societies. He will at once take up the task of organizing this new and important work, which is designed to become a sort of international health department and general clearing house for the exchange of information on public health activities in all parts of the world. Professor Whipple will continue until February in his work at Harvard, where he is secretary of the School of Public Health and professor of sanitary engineering.

Professor Whipple is widely known as an authority on water supply. His work has carried him to various parts of the United States, and as deputy commissioner of the American Red Cross Mission to Siberia, brought him into contact with the sanitary needs of many countries.

AMERICAN LIFE INSURANCE MEDICAL PROGRAM

One of the interesting features of the medical program of the American Life Convention at French Lick Spring, Ind., held March 10 to 13, 1920, was the illustrated lecture on influenza given by Dr. A. C. Page, medical director of the Provident Life Insurance Company, of Des Moines, Ia.

Dr. Charles Lyman Greene, of St. Paul, Minn., discussed at some length the pertinent application of the "soldier's heart" to the common but formerly unrecognized civilian ailment. "Rating Physical Impairments," constituted the contribution of Dr. H. A. Baker, Medical Director, Kansas City Life Insurance Co., and an interesting and valuable analysis of "The American Men Mortality Rate" was made by Robertson G. Hunter, Vice President and Actuary of the Equitable Life Insurance Company, Des Moines, Ia.

PENNSYLVANIA INDUSTRIAL PHYSICIANS CONFER

On the last day of a four-day Safety Congress to be held in Harrisburg, Pa., the last week in March, the Pennsylvania Department of Labor and Industry will hold its Tenth Annual Conference of Industrial Physicians and Surgeons. The personnel of the leaders of the discussions, and the nature and range of the industrial health topics treated afford assurance of the value of the material presented. Their program follows:

Chairman: Dr. Francis D. Patterson, Chief, Division of Industrial Hygiene and Engineering, Pennsylvania Department of Labor and Industry.

Address of Welcome. By Hon. Clifford B. Connelley, Commissioner, Pennsylvania Department of Labor and Industry.

The Rehabilitation of the Industrial Cripple. By Dr Harry E. Mock, President, American Association of Industrial Physicians and Surgeons, Chicago, Illinois.

The Problem of the Malingerer. By Dr. Judson C. Fisher, New York City.

Heart Disease in Relation to Industrial Efficiency. By Dr. William E. Robertson, Philadelphia, Pa.

The Physically Substandard Worker. By Dr. Irving Clark, The Norton Company, Worcester, Mass.

Influenza. By Dr. Alfred Stengel, professor of medicine, University of Pennsylvania, Philadelphia, Pa.

Health Education in Industry. By Dr. C. E. Ford, General Chemical Company, New York City.

Plant Dispensaries and Their Equipment. By Dr. C. D. Selby, Toledo, Ohio.

Occupational Diseases and Their Compensation. By Dr. Frederick Hoffman, Third Vice President, Prudential Insurance Company of America, Newark, N. J.

HEALTH CAMPAIGN IN NEW YORK

A health campaign is being instituted in New York City by the United Neighborhood Houses. Plans have been laid by the Association to establish in every community where there is a neighborhood house a health center which will work intensively along the line of social hygiene, nutrition, tuberculosis, and maternity protection.

MINNEAPOLIS UNDERTAKES SAFETY WORK

The Minneapolis Civics and Commerce Association stands sponsor for a safety campaign which will promulgate safety measures in both public and industrial fields. Dr. C. H. Kohler has been appointed acting chairman of the local safety council. Dr. Kohler, supported by the Committee on Accident Prevention of the Civics and Commerce Association, is working out the details of organization with W. R. Rasmussen, regional field secretary of the National Safety Council.

AMERICAN PHYSICAL EDUCATION ASSOCIATION

The convention program announced for the meeting of the American Physical Education Association announced to take place April 7-10, 1920, in New York City, contains the names of a number of authoritative speakers and a range of subjects that command the interest of both professional and lay workers. Prof. E. L. Thorndyke, of Columbia University, will discuss "Educational Tests for Physical Efficiency." Prof. Irving Fisher is scheduled to give an address on "Health and the High Cost of Living." Prof. Frederic S. Lee, of Columbia University, is scheduled for an address, and Dr. George E. Vincent, president of the Rockefeller Foundation, will talk on "Relation of Physical Education to Leisure Time in Industry."

NATIONAL CONFERENCE OF SOCIAL WORK

The National Conference of Social Work will convene in annual session in New Orleans April 14-21, 1920, just preceding the meeting of the American Medical Association. Reports of the activities of the Organization will be made under ten departmental sections dealing with children, delinquents, health, public agencies, the family, industrial and economic problems, the local community, mental hygiene, the organization of social forces, and Americanization.

The opening evening will be devoted to addresses by the president of the Organization, Owen R. Lovejoy, who is also secretary of the National Child Labor Committee; by Felix Adler; and by Randall J. Condon, superintendent of the Cincinnati, O., public schools.

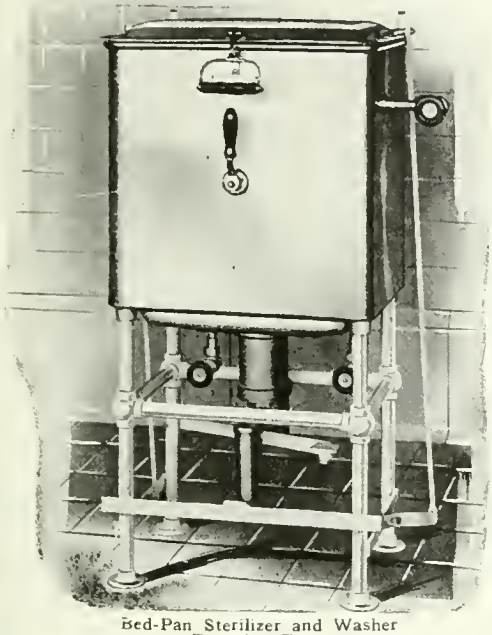
Addresses on health topics will include a contribution by Dr. Royal Meeker on the relationship to standards of living. Recent health legislation will be reviewed, and the health work of the Red Cross will be considered. One meeting will have as the subject of discussion the social responsibilities of the hospital.

The Division on Mental Hygiene is under the direction of Dr. C. Macfie Campbell, of Johns Hopkins University and Hospital. This Section will present a study of the supervision of the mentally handicapped outside of institutions. The mental hygiene of industrial work will receive consideration. An interesting and valuable feature in this Section will be a summary of the materials developed by the late Dr. E. E. Southard, of Harvard University.

"AMERICAN"

THE PRODUCT OF SPECIALISTS

BUILDINGS versus EQUIPMENT



Bed-Pan Sterilizer and Washer
Dumping Type

The reputation of an institution does not depend so much upon the character of the buildings that house it as upon its PERSONNEL and its WORKING EQUIPMENT.

Beyond a certain point anything that may be added to the exterior becomes an embellishment—beautiful but not VITAL.

Proper sterilizing equipment is vital.

Next in importance to the human element in any undertaking are man's mechanical aids. Doubly so is this true of the Surgeon's work.

"AMERICAN" sterilizers are built to be worthy of this important role. DEPENDABLE, EFFICIENT and EASY OF OPERATION—they have gained the front and have kept it. Investigate "AMERICAN" sterilizers and you will find that the secret of their success is HIGHEST QUALITY and LONGEST SERVICE.

AMERICAN STERILIZER COMPANY, Erie, Pa.

The Coffee Problem

We have solved the Coffee problem for Hospitals, Sanitariums and other institutions in our coffee plant. It is a large factor in our ability to supply a standardized product—to maintain a uniformity in the roasting and blending processes whereby we can meet continuously and confidently the requirements of our customers for coffees which they have found to their liking and in which they wish no variation as they purchase from time to time.

Many of our customers simply say: "Send us another drum of our coffee." Our records show what is wanted in each case, and our method enables us to duplicate exactly every time. This is our coffee standardization plan, by which we render a reliable and pleasing service.

Roasting and Cooling.

Grinding and Packing.

Bins for Various Blends.

ARISTON COFFEE-CEREAL BLENDS

And don't forget our Ariston Coffee-Cereal Blends, whereby we provide you a perfect coffee beverage (not in any sense a substitute), with real food value, reduced caffeine content, and at a substantial price saving. Only by trial can you know the merit of these blends, which are especially valuable for hospital use in serving patients who ought not to drink straight coffee.

Furnished in the following blends:

Ariston Coffee-Cereal Blend, No. 1, per lb.	$0.38
Ariston Coffee-Cereal Blend, No. 2, per lb.	.36

SCHOOL FOR PUBLIC HEALTH NURSES

A sixteen weeks' post-graduate course for public health nurses is provided under the auspices of the Buffalo University (New York), the Buffalo chapter of the American Red Cross, the Department of Health, the District Nursing Association, and the Department of Hospitals and Dispensaries. The excellent teaching staff and the facilities for practical work afford opportunities of unusual value for special training in this field.

HEADS NORTHERN DIVISION RED CROSS

Announcement is made of the appointment of Dr. Mabel Ulrich, of Minneapolis, as a director of the new health service department of the Northern Division, American Red Cross. Dr. Ulrich has been on the staff of the Minnesota State Board of Health, and is chairman of the public health committee of the Minneapolis Board of Public Welfare. She has been a national lecturer on social hygiene for the Young Women's Christian Association.

HEALTH CENTERS FOR ALL NEW YORK BOROUGHS

Plans are under consideration by the Department of Health of the city of New York for the establishment of health centers in all boroughs of the city. Each of the new centers is to be a miniature health department where advice will be furnished on any subject relating to public welfare and where the various functions of the health department will be coordinated. Each of the five borough offices has already been equipped with a clinic where vaccinations are performed, food handlers examined, and mothers can go for advice. An expert from each of the bureaus—preventable diseases, child hygiene, food and drugs, vital statistics, and the sanitary bureau—has been assigned to the various borough offices.

FORM NEW TUBERCULOSIS ASSOCIATION IN NEW YORK CITY

The anti-tuberculosis work in New York City which for the past seventeen years has been thoroughly and energetically carried on by the Committee on the Prevention of Tuberculosis of the Charity Organization Society, has been taken over by a new and larger corporation, the New York Tuberculosis Association, Inc. All the members of the old committee, including such prominent workers in the tuberculosis field as Dr. Hermann M. Biggs, state commissioner of health; Dr. Royal S. Copeland, health commissioner of New York City; Mr. Lee K. Frankel, Dr. S. S. Goldwater, Mr. Thomas W. Lamont, Dr. S. A. Knopf and others are members of the board of directors.

The objects of the Association are: the study of tuberculosis and of the means of preventing it; the dissemination of knowledge as to the nature of the disease, its causes and the methods of its prevention and its treatment; the promotion of adequate facilities for the prevention of tuberculosis and for the care, treatment and economic rehabilitation of persons afflicted therewith, and the coordination of the work of public and private agencies engaged in any of the foregoing activities.

Dr. James Alexander Miller is the president of the Association and Mr. Homer Folks is the vice president. Dr. John S. Billings, long connected with tuberculosis work in New York City, is the Director.

Among the secretaries so far appointed are: Mr. G. J. Drolet, statistician; Miss Gretta Jones, relief organizations; Mrs. Josephine Toering, tuberculosis dispensaries; Mr. E. C. Rybecki, labor; Mr. David Ryan, publicity.

MODERN MEDICINE

NOTES AND COMMENT

HEALTH CENTERS IN NEW YORK

THE health recommendations of Alfred E. Smith, Governor of New York, urging the necessity of extending facilities for the conservation of health, emphasized the present tendency of physicians to concentrate in the centers of population. Many of the rural districts in New York have been practically abandoned, resulting in a situation so inimical to public welfare as to call for a redistricting of the state which will enable each district to support a proper health administration and bring all distric tusnder state supervision. The solution is to be found in health centers which provide full-time health officers, consultant and laboratory service, hospital care, and efficient home nursing. It is expected that these centers will provide facilities for group practice that will counteract the tendency of physicians to locate in the cities.

Following the recommendations of Governor Smith, there has been prepared and introduced in the legislature of New York a comprehensive bill providing for the wide extension of medical service through public facilities. Probably never before in the history of this country has so far-reaching a measure been proposed by responsible authorities.

Modern Medicine presents in this issue the summary of the bill prepared by the New York State Department of Health. In brief, the purposes, as stated by the department, are as follows:

(1) To provide for the residents of rural districts, for industrial workers and all others in need of such service, scientific medical and surgical treatment, hospital and dispensary facilities and nursing care, at a cost within their means or, if necessary, free.

(2) To assist the local medical practitioners by providing: (a) Facilities for accurate diagnosis by a coordinated group of specially qualified physicians and surgeons, both for hospital patients and for out-patients. (b) Consultations and advice as to treatment by medical and surgical experts. (c) Clinical, bacteriological and chemical laboratory service and X-ray facilities at moderate cost or free when necessary.

(3) To encourage and provide facilities for an annual medical examination to detect physical defects and disease and to discover conditions favorable to the development of disease, and to indicate methods of correcting the same.

(4) To provide or aid in securing adequate school medical inspection and school nursing service (in cooperation with the Department of Education).

(5) To secure or aid in securing better enforcement of the Public Health Law and a more effective administration of Public Health activities within the area served.

(6) To provide a Public Health nursing service adapted to and adequate for the community served.

(7) To aid in securing the dissemination of information in regard to Public Health throughout the area served.

(8) To aid in securing adequate compensation for medical and surgical care rendered in hospitals and clinics, in order that efficient service may be everywhere available.

(9) To provide laboratories, group diagnosticians, consultants, and hospital facilities in the smaller cities and rural districts, and to counteract the growing tendency of medical practitioners to remove to larger centers, and to attract to and to retain in the practice of medicine in these communities a larger number of qualified practitioners of both sexes.

(10) To provide medical libraries including books, pamphlets, periodicals, leaflets, exhibits, moving picture films, and kindred educational facilities, with halls for meetings if needed.

(11) To provide hospital and other necessary resources for dealing promptly with epidemics.

(12) To reduce illness and disability among the industrial workers of the state by providing prompt and

accurate diagnosis and efficient treatment for sick and injured workers and the members of their family.

(13) To coordinate public health activities within the districts.

The progress of this measure will be watched with keen interest by physicians and social workers. That there will be divergence of opinion must be expected. The bill innovates so much on old systems that the conservative is likely to hold back. Those who have caught the vision of the new mission of medicine, however, may be expected to join their approval heartily with this measure.

SIR AUCKLAND GEDDES AND SOCIAL RECONSTRUCTION

PHYSICIANS both in America and in England are gratified at the recognition given to an honored member of the medical profession by the selection of Sir Auckland Geddes as British Ambassador to the United States. Sir Auckland is a physician and a teacher of physicians and, in addition, has had a brilliant experience as Minister of National Service in the cabinet of Lloyd George. Moreover, he is a medical statesman who sees beyond the present to the greater function which medicine may perform in the newly reconstructed world.

Special interest attaches to the views of Sir Auckland concerning the medical profession in the new era. Americans are privileged to secure such a view in the volume of "Contributions to Medical and Biological Research" dedicated to Sir William Osler, which has just come from the press. In this volume, under the title "Social Reconstruction," Sir Auckland gives a vision of the opportunity of the physician. "We are at this moment," he says, "in the power of a world-wide emotional storm the full effect of which is not yet manifest. Is the Armada of civilization to be dashed to pieces on the rocks now almost beneath our bow? The issue may well be in doubt for years to come. It depends largely, though by no means exclusively, upon the medical profession.

"Much of the new chart that is now preparing has to do with physical health and clearly can be accurately plotted only by men who know the achievements and limitations of medical science. Already the politician and the civil servant, untrammeled by medical knowledge, are becoming health experts and are at work plotting the chart. There is great danger in this, but it is useless to cry for spilt milk. It is peculiarly useless for the medical profession to cry, for the pitcher was in their hands. If only we can round the rugged promontory of the next few years, and if the future be consciously and conscientiously prepared in the universities, in the schools, aye, in the nurseries, and if the medical profession clearly and carefully speak the truth, so many correctly plotted points may be added to the chart of human life; then the fleet of humanity will come safe to port in spite of all. We cannot hope that every point plotted will be correctly placed. We cannot hope so much from this generation of doctors as we may rightly expect from the next; but if we could all see, as I believe many medical men in English-speaking countries do, a little further and a little more clearly than the lay world in the direction in which the emotion of human betterment is driving us, then the now middle-aged might live to rejoice at the recognition of medical science as the main basis of political action, for all political action aims nominally at least to secure the health and well being of the people."

Sir Auckland criticizes the training of physicians because it does not develop citizenship. He declares that doctors are "immature citizens," with their knowledge of citizenship "divorced from their technical knowledge." Discussing this point further, he declares that "the measure of failure of the medical profession is to be found in the revelation of the recruiting medical boards, and in such documents as the Report of the Royal Commission on Housing in Scotland. If the medical profession had been using its technical knowledge in the interests of the State as a whole, it would have been insistent years ago in the demand for better housing, for better feeding, for better wages, for shorter hours of labor, not for itself but for the toiling millions to whom it ministers. Isolated voices were heard, but the demands that could not have been resisted were never made. The profession had only to organize its own knowledge and tell the truth about the conditions of the lives of the workers to compel the emotion of human betterment throughout the world to force action."

Fortunately, Sir Auckland sees the prospects of better conditions both for the world and the medical profession. He finds this prospect in the newly released force of womanly instinct and emotion. "The male," he says, "in virtue of a million years of war, is a fighter," for whom the day in which he lives and the action of today "are more important than the morrow which he may never see, or the fruits of autumn which he may never know." On the other hand, the instincts of motherhood teach women to see in the child the adult that is to be. Thus, while the male "is equipped to fight the invading bacillus for his patient's life," the female reacts as surely to "the slow drawn torture of over-work and bad housing."

VICTOR C. VAUGHAN, M.D., President, National Tuberculosis Association

ALEXANDER LAMBERT, M.D. President, American Medical Association

ELLA PHILLIPS CRANDALL, Executive Secretary, National Organization for Public Health Nursing

DR. WM. C. BRAISTED, Surgeon General, United States Navy, President-Elect, American Medical Association

HARRY E. MOCK, M.D., President, American Association of Industrial Physicians and Surgeons

THE annual meetings scheduled for April show a greatly broadened interest in medical topics and their several programs are of unusual interest. The American Medical Association will convene in New Orleans April 26-30, under the presidency of Alexander Lambert, M.D.

The growing sense of the civic responsibility of the physician is shown in the range of medico social subjects covered by the program of the American Association of Industrial Physicians scheduled for April 25-26. The two-day session in New Orleans in advance of the American Medical Association should be well attended.

The National Tuberculosis Association is to be held in St. Louis April 22-24, the place and date making it a convenient stop-over en route to New Orleans.

The National Organization for Public Health Nursing will meet in Atlanta April 12 to 17 under the presidency of Katherine Tucker.

THE CONTRIBUTIONS OF LAYMEN TO MEDICAL SCIENCE

By JAMES A. TOBEY, American Red Cross, Washington, D. C.

THE history of medicine contains many instances of doctors who have excelled in arts and sciences other than their own. Avicenna was a great geologist. Two of the popes, John XXI and Paul II, were physicians. Goldsmith and Schiller were medical graduates and Rabelais was a priest and physician. It is said that Haller lost the election of doctor to the hospital of his native city on the ground that he was a poet. Claude Bernard was another who invoked the muse. In recent times Drs. Oliver Wendell Holmes and S. Weir Mitchell are best known to the general public as literary men. Leonard Wood is thought of as a distinguished soldier and statesman, though most people are familiar with his early medical training. And so on, one might cite innumerable examples of doctors who have enriched other fields of endeavor with their work.

Versatility of Scientists

The converse is also true that medical science has profited greatly by the discoveries and developments of those who are classed as non-medical. Our present day conception of a "layman" is a person who does not possess a medical degree. Previous to the beginning of the nineteenth century a layman may be defined as one who was not actively a professor or practitioner of medicine. It would hardly be fitting to call John Hunter, the greatest of anatomists, a layman, though his education was only that of the school of experience. On the other hand, Thomas Huxley was a medical graduate, but his life work was preëminently that of a naturalist and he is not classed as a medical man.

General science in the medieval ages and even in the period following Renaissance was of a character that permitted men to be masters of several branches of it. Today the scope of learning is so vast that more often a mastery of only a part of one branch of science is possible. In the fifteenth century, for instance, it was no unusual thing for a scientist to be described as a mathematician, astronomer, alchemist, philosopher, and physician. The term "Doctor of Medicine" was first applied to graduates of the University of Salerno in the twelfth century. Examinations to practice medicine were first held in 1140 in accordance with an edict of Roger II of Sicily. In 1224 his grandson, the Emperor Frederick II, issued a broader requirement in which the candidate had to be examined in public by the masters of Salerno. The test was based on the books of Hippocrates, Galen, and Avicenna, and the previous training of the candidate must have included a study of logic for three years, medicine and surgery for five years, and a year of practice for one year under the direction of an expert.

SCIENCE IS CUMULATIVE

Time was when the man of vision worked alone in his laboratory. His detached discoveries were slow to find credence, and their application in other fields was not readily understood.

With the appreciation that all matter is similarly constituted, that physical laws are universal, that nothing is isolated but everything interacts, came the correlation of the sciences. The greatest man in any field is the one who sees facts in their largest relationships. No science can stand alone, nor are the fruits of research for the esoteric, but must contribute their quota to science and to civilization.

There is no time in an essay of this character to attempt to take up the many discoveries which had an indirect bearing on medicine, such as the invention of printing or the laws of gravitation; in fact, there are so many discoveries by laymen that have had a direct influence of importance on medical science that only some of the more significant of these can be mentioned. As Oliver Wendell Holmes writes in his "Medical Essays," "Medicine . . . appropriates everything from every source that can be of the slightest value to anybody who is ailing in any way, or likely to be ailing from any cause. It learned from a monk how to use antimony, from a Jesuit how to cure agues, from a friar how to cut for stone, from a soldier how to treat gout, from a sailor how to keep off scurvy, from a postmaster how to sound the eustachian tube, from a dairy maid how to prevent small-pox, and from an old market woman how to catch the itch insect. It borrowed acupuncture and moxa from the Japanese heathen, and was taught the use of lobelia by the American savage"

In his book entitled "Pathfinders of Medicine" Victor Robinson devotes chapters to Ambroise

Paré, the surgeon; Scheele, the apothecary, Cavendish, the chemist, Jenner and vaccination, Schleiden and Schwann, and to Darwin, the saint of science. There are fifteen chapters and six of them are about non-medical men. Some sixteen years ago Dr. George M. Gould wrote a long and interesting article on "Medical Discoveries by the Non-Medical" for the *Journal of the American Medical Association.*

The Mechanics of Surgery

Although believed to be more ancient than medicine, surgery did not become a part of medical science until the time of John Hunter (1728-93). The invention of gunpowder by Berthold Schwartz in 1330 caused a reform in existing methods of surgery. Its practice was in the hands of strolling mountebanks, bath keepers, and barbers. The creator of surgery was one of the latter. He was Ambroise Paré, born in 1510. He served as a barber's apprentice and as a dresser until he became an army surgeon in 1537. Though treated contemptuously because of his lack of education and because he wrote in French instead of Latin, he soon became the acknowledged leader in surgery and served as surgeon for three kings of France. He reformed the treatment of gunshot wounds and contributed much to obstetrics. He is also credited with being the first to accuse flies of carrying disease.

In gynecology the first cesarean section was performed by a sow gelder, Jacob Nufer, in 1500. Another sow gelder is said to have done a double ovariotomy on his daughter a few years later. The French midwife, Louise, wrote an authoritative treatise on obstetrics the latter part of the sixteenth century and an English family devoted to midwifery, the Chamberlains, invented an obstetric forceps about 1670, which they kept as a family secret for two hundred years.

Eli, a strolling quack, is credited with the first perforation of the tympanic membrane for deafness. A French postmaster, Guyot, first attempted the catheterization of the eustachian tube in 1724. A London singing master, Garcia, invented the laryngoscope, and drainage tubes were first made by Captain Creighton in 1730. Chloroform was discovered in 1831 simultaneously by Dr. Guthrie, and by the chemists Soubeiran in France and Liebig in Germany. Ether was introduced principally by two dentists, Horace Wells, in 1844, and W. T. G. Morton, in 1846, in the United States.

The physicists have contributed much to the advancement of medicine. Dr. Roswell Park, in his "Epitome in the History of Medicine," remarks: "The laws of physics have been shown to have an inseparable connection with anatomy and physiology; through Helmholtz they brought the ophthalmoscope; thermal electricity, for the discovery of which medicine is indebted to Seebeck; a better knowledge of optics, thanks to Fraunhofer, who was equally expert in electricity; spectrum analysis, invented by Kirchoff; and the varied efforts of Faraday, Graham Bell, Thomas Alva Edison, and Daguerre, the latter known for his invention of photography. Finally, medicine is immeasurably indebted to Tyndall and Huxley for their teaching of the correlation and conservation of energy."

The whole subject of ophthalmology was developed by the physicists and astronomers. Kepler, an astronomer, wrote an epoch making treatise on vision in 1604. He discovered that the crystalline lens was not the seat of vision as had been supposed, but that its function was for the refraction of light, like other lenses. Interest in the anatomy of the eye was aided by the researches of Newton on light and color. Before Helmholtz, a layman, Babbage, had devised an instrument for looking into the eye. Benjamin Franklin (1706-90) invented bifocal lenses in 1785. Franklin also invented a flexible catheter, advocated treatment of mental disease by electricity, and wrote numerous letters on various medical subjects. Electro-physiology received its impetus from the work of Volta and Galvani.

Another physicist of note, whose doctrines were of importance to medicine was Francis Bacon (1561-1626). Dr. David A. Gorton, in his "History of Medicine," states "the name of Francis Bacon does not usually appear in the galaxy of great names in medicine. Nevertheless, it deserves a place there. He was not a physician, it is true, except in the sense that he was a philosopher, and a man, therefore, whose grasp of things embraced the whole of nature and therefore of man. . . . He gave a great impetus to science and conferred an incalculable benefit upon medicine by recalling to the attention of men the proper way to approach the study of the phenomena of disease." Among other things, Bacon discovered the law of the transmission and reflection of sound in 1624.

The theory of respiration was, in the words of Dr. F. H. Garrison, "from Borelli to Magnus, almost exclusively the work of three mathematicians, two physicists, and five chemists." Borelli (1608-79), a mathematician, originated the neurogenic theory of the action of the heart. Respiration was worked on by Robert Boyle, the chemist, and by Robert Hooke, in the middle of the seventeenth century. Intravenous injection was first performed by the architect, Sir Christopher

Wren, assisted by Boyle, in 1656. He was the first to urge transfusion and Boyle the first actually to perform it on animals. In 1666 Denys, a professor of philosophy and mathematics, performed the experiment on human subjects. The completion of the theory of respiration was due to the discovery of different gases of the atmosphere by the chemists Black, carbon dioxid in 1757; Cavendish, hydrogen in 1766; Rutherford, nitrogen in 1772; Priestly and Scheele, oxygen in 1771; and Lavoisier, oxygen in 1775. The latter demonstrated with Laplace, the astronomer, that respiration is analogous to combustion. Further studies were made by Lagrange, and by Magnus, who used Spregel's air pump in his experiments.

The Principle of Inoculation

Vaccination was introduced by Edward Jenner in 1796, when he applied his observations of the fact that dairy maids who had cowpox did not contract small-pox by vaccinating a country boy, James Phipps. Jenner was a country gentleman who drifted into the practice of medicine. He attended no medical school, though he studied for a while under John Hunter. He was a licensed practitioner, however. Inoculation against small-pox had been practised by many ancient peoples and the practice was introduced into England by Lady Mary Wortley Montagu in 1721. Vaccination had already been performed before Jenner by the Dorset farmer, Benjamin Jesty, in 1774; and again his doctor had done it in 1789.

The development of the microscope was of importance to medicine. It paved the way for the science of bacteriology and for the cellular theory, which is one of the fundamental principles of modern science. Its use completed the demonstration of the circulation of the blood, as discovered by Harvey in 1628. The earliest microscopist was the Jesuit Kircher, who has been described as a mathematician, physicist, optician, Orientalist, musician, virtuoso, and physician. He was born in 1602. Another early worker was Robert Hooke (1635-1703), a physician and mechanical genius. Others who did work in this line were Grew, a botanist; and Swammerdam, a naturalist. Antony van Leeuwenhoek, another naturalist, had 247 microscopes and 419 lenses, most of which he had ground himself. He was the first to see Protozoa under the microscope, and made many other important discoveries. Hooke invented a compound microscope in 1665.

The cellular theory was developed almost entirely by botanists. Robert Brown found the cell-nucleus in 1831, and Gabriel Valentin the cell-nucleolus in 1836. The greatest researches were made by Schleiden, a botanist, and Schwann, a physiologist. The latter also discovered pepsin and demonstrated that bile is indispensable to digestion. At this time, early in the nineteenth century, much progress was made toward the germ theory of disease and the microscope was further developed. The chemists Liebig and Wohler also made experiments which gave rise to the theory of the chemistry of metabolism. The latter first made urea synthetically.

Biology and Bacteriology

General biology was fostered by the epoch making treatise on the "Origin of Species" by Charles Robert Darwin (1809-1882) in 1859. Darwin started on this work in 1838 and so antedated Alfred Russel Wallace (1882-1913) who arrived at the same theory independently in 1858. The idea of evolution is, of course, the salient feature of modern science. It had been thought of by the Greeks and had been mentioned and even outlined by such thinkers as Bacon, Goethe, Lyell, and Herbert Spencer; but it was Darwin's wonderful marshaling of the facts that had the most influence on the development of the theory. Out of this grew the sciences of comparative physiology, cellular pathology, bacteriology, and parasitology—all of the utmost importance to modern medicine. A follower of Darwin was Thomas Huxley (1825-95), who was an entertaining writer and one who did much to popularize scientific essays.

Bacteriology as a science was founded by Louis Pasteur, a chemist, and Robert Koch, a physician. Pasteur was born in 1822. His whole life was one of brilliant achievements and modern preventive medicine owes more to him than to any other one man. The first of his classic studies was in 1848 and resulted in showing the conversion of dextro-tartaric acid into racemic and mesotartaric acid by means of penicilium glaucum. From these studies he became interested in fermentation and microörganisms in general. He showed in 1857 that fermentation is a vital process due to microörganisms, and not a chemical one as had been thought. He next disproved the theory of spontaneous generation by showing the value of sterilization. Lister later applied this to surgery. When the silk worm industry of France was threatened with destruction by disease in 1865, Pasteur was employed to find the cause, which he did and which proved to be a microbe, or parasite. Again, when chicken cholera, as it was called, broke out in France, he found the microbe and also accidentally discovered that attentuated cultures of it would prevent the disease. Out of this fact came preventive inoculations. Pasteur's other studies were on the

diseases of wine (1863), anthrax (1877). At the same time he worked on the chicken cholera, and rabies in 1885. He produced a vaccine for anthrax in 1881 and he, also, though several years earlier, discovered the *Staphylococcus pyogenes*, which causes boils. His principle of killing bacteria by heat is applied for the protection of all foods, as by the pasteurization of milk.

Among Pasteur's pupils was Metchnikoff, who has done important work on phagocytosis. With Roux, another pupil, in 1903-4, he first showed that the higher apes could be inoculated with syphilis. In 1905, Schaudinn, working with Hoffman, discovered the cause of syphilis, the *Spirochacta pallida*. Thus, the first steps in the control of this disease were made by two zoölogists, Metchnikoff and Schaudinn. Paul Ehrlich, who produced salvarsan, was educated as a physician, but spent most of his life working as a chemist and pharmacologist.

Public Health Work Develops

The sanitation of hospitals and the reform of nursing was due to the efforts of an Englishwoman, Florence Nightingale (1823-1910). She went to the War of the Crimea in 1854, and her work there is a matter of history. She published her "Notes on Nursing" and on her return to England was instrumental in starting a training school for nurses. Thus, a new profession was opened to women, the scope and usefulness of which needs no elaboration here.

Public health in this country has been greatly advanced by the work of sanitary engineers and non-medical sanitarians. The first course in sanitary engineering in this country was given at the Massachusetts Institute of Technology, and graduates of this course and of that of Biology and Public Health, begun in 1886, of the same college, have played an important part in the hygiene and sanitation of the United States. Water supply, sewage disposal, ventilation, vital statistics, and much of industrial hygiene have been developed by such non-medical men as W. T. Sedgwick, G. C. Whipple, C-E. A. Winslow, A. Hazen, H. F. Mills, E. B. Phelps, E. O. Jordan, S. M. Gunn, F. L. Hoffman, Irving Fisher, L. K. Frankel, L. Dublin, E. Huntington, J. B. Andrews, S. C. Prescott, and E. C. Meyer, who have been prominent in other branches of public health as well. Every medical school and college which gives courses leading to degrees in public health in this country makes provisions for non-medical men to qualify as health experts. It might be mentioned in passing that medical education in the United States owes much of its present high caliber to the studies of a non-medical man, Flexner, in 1909-11.

A few miscellaneous discoveries which have not been mentioned in any of the sections above may be inserted here. Between 1593 and 1597 Galileo invented a thermometer and Kepler first counted the pulse in 1600. Quinin was introduced as a cure for malaria in the seventeenth century by a Jesuit who obtained the bark from the natives of Peru. He used it to cure the wife of the Spanish governor and gave the drug the name of cinchona in her honor. Balsam was discovered by a Portuguese monk in Brazil about 1600. Arsenic was introduced into England in consequence of the success of a patent medicine. The Tasteless Ague Drops and Colchicum came in a similar way from the Eau Medicinale of a French officer. Iodin was discovered by a saltpeter manufacturer. The cure of scurvy is credited to Captain Cook, the explorer. Sir Humphrey Davy assisted industrial hygiene by his invention of the miner's safety lamp in 1815. The discovery of the x-ray by Roentgen in 1893 has been of great value to modern surgery. The science of eugenics owes its basis to the law of the Augustinian monk, Gregor Mendel, a principle which, while pronounced in 1865, was not given any particular attention until 1900. The further developments of this doctrine were the work of Francis Galton, who laid the foundations for the science of biometrics, which differs considerably from Mendel's law. Galton first applied the term "eugenics." Most of the drugs of recent times have been the results of experiments by chemists, an example being veronal, which was produced by Fischer in 1904. Radium, discovered by Curie, also has a therapeutic value.

Thus, it is seen that along with the vast achievements of the great physicians of all times, there have also gone many contributions to medical science by chemists, physicists, mathematicians, astronomers, botanists, naturalists, zoölogists, physiologists, philosophers, ecclesiastics, sanitary engineers, and various other types of common humanity. Science is, however, a unitary thing. All branches of it overlap. What difference does it make whether a man be a doctor of medicine, of philosophy, or of science, if he produce something of permanent value? It is the man and not his title which counts. To contribute to science and hence to civilization and humanity is the privilege and, further, the duty of all mankind.

DR. RICHARD CLARKE CABOT

Dr. Richard Clarke Cabot, professor of clinical medicine at Harvard Medical School and chief of the West Medical Service of the Massachusetts General Hospital, has been appointed Professor of Social Ethics at Harvard College. Dr. Cabot enters at once upon his new duties, at the same time continuing his present connections.

THE NEW YORK HEALTH CENTER PLAN AND MEMORANDUM*

The increase in knowledge of the medical sciences in recent years has become so great, has progressed with such rapidity, and has come to cover such a variety of subjects, that it has long since become impossible for any one man to keep abreast of all the branches of medical work. Furthermore, large experience and great technical skill and dexterity are required as never before in many lines of laboratory and clinical diagnosis of disease and in the practice of medicine.

Relation of Collateral Sciences

A wide general educational training is required of physicians, for medical science is not only closely related to but is absolutely dependent upon a knowledge of several collateral sciences, such as biology, physiology, chemistry, physics, and bacteriology; and furthermore, full knowledge of the progress in medicine is only possible if one is familiar with one or two of the modern languages. It has accordingly come about that specialization in medicine has developed to a high degree and there is now a vast difference in many cases of sickness between the results obtained in treatment by a highly qualified specialist using all the resources of medical science, and those ordinarily obtained from treatment by a general practitioner with few or none of these aids.

The complete and accurate diagnosis of disease is almost always difficult, often at best is only approximate and demands all the resources of modern medicine, including the aid of experts for its accomplishment. Experience has further shown that the best results in diagnosis and treatment can only be obtained by the coordinated efforts of a group of specialists working together. This association has come to be known as "group medicine." There is no place in the world where this kind of work has been developed to such a remarkable extent and with such signal success as at the Mayo Clinic in Rochester, Minn. There, in a small country town in an agricultural district has been built up, largely as a result of the employment of this method of practice, the most important surgical clinic in the world, the activities of which are conducted at present by more than 160 physicians and surgeons, many of them highly trained experts in the various phases of medicine and surgery and in the contributory sciences. To this place 60,000 or 70,000 people go each year.

It is not usually recognized that while medical science has made extraordinary advances during the last twenty-five years, the benefits resulting from the new discoveries are at present available, generally speaking, to a very small fraction of the population only. It is indeed in the larger centers of population and especially in connection with teaching institutions and large hospitals that the best type of modern medical practice is available. Furthermore, it is noteworthy that while this great advance is going on, in many of the smaller cities and in the rural districts for a number of reasons the conditions of medical practice are changing, not for the better, but rather for the worse. Some of the reasons for this are as follows:

(1) The number of physicians in practice in small cities or rural districts is steadily decreasing. Only one-half as many physicians are now being graduated each year from the medical schools of the country as were graduated twenty years ago, and the number of medical schools has decreased more than one-half. The quality of teaching in the remaining schools has greatly improved; but it is the general opinion of teachers of medicine that the quality of men who are taking up the study of medicine has deteriorated. The rewards in the practice of the profession are not commensurate with the long period of study required, the cost involved, and the self-sacrificing life which the practice of medicine entails.

To commence the study of medicine at the present time in New York State, a man must not only have been a high school graduate, but most have had at least two years' instruction in an institution of collegiate rank, including courses in biology, physics, chemistry, physiology, psychology, and at least one modern language. A four years' course in a medical school is then required, and at least one and often two years' internship, without compensation, in a hospital. After receiving his degree, before a graduate in medicine can undertake to practise, he must take a licensing examination before the State Board of Medical Examiners. In other words, after a man has finished the course in one of the best high schools he must continue his work for seven or eight years before he can commence to earn his living, and then he learns that the compensation in all professional positions open to physicians is totally inadequate and relatively much lower than that of other professions, and to fit himself further for a successful career by gaining the experience which is necessary for the successful private practice of medicine he is expected to serve without compensation for most of his professional life on the staff of dispensaries, hospitals, and other institutions. The medical graduate is generally fortunate if he succeeds in making his living after three to five years of practice, when he will probably be more than thirty years of age.

More than one-half of the health officers of the state of New York receive as compensation for their health work less than one hundred dollars a year. Fifty-eight districts of the state have appealed to the Health Department to send them physicians, as they were totally without medical service. In one typical rural county where there were fifty-two physicians an investigation by the State Department of Health showed that these physicians had been in practice twenty-eight years on an average, and that during the last ten years only four new physicians had commenced practice in the county. Hence, it requires little vision or imagination to see what will be the condition in that county ten or twelve years from now unless some change in the situation is brought about.

(2) Not only is medical service wanting in many districts, but trained nurses are also lacking and, where they are available it is becoming more and more impossible for the average individual to obtain or to pay for their services. Many of the trained nurses in the cities and rural districts are now receiving six dollars per day and board for twelve-hour service. This means that in case of serious illness two nurses are required and the cost is $12 a day plus the board of the nurses. When this expense is added to that of medical services, medicines, and medical supplies, a daily cost of $20, or more,

*This plan and memorandum were prepared by the State Department of Health to carry out the recommendations of Governor Alfred E. Smith of New York, made to the legislative session of 1920.

possibly $25 or $30 per day—an amount which the average person can not afford to pay.

Organization for Service

(3) Domestic servants are no longer to be obtained except with great difficulty and sometimes not at all in the smaller cities and the rural districts; and when people are seriously sick, owing to the lack of physicians, nurses, and domestic servants, it is becoming more and more imperative that if they are to receive even ordinary care they shall be removed to a hospital. The hospitals available are often inadequate and generally are not so organized as to give the best kind of medical and surgical service. Hence, the broad purpose of this Bill is to make efficient medical and surgical practice more generally available; to provide to physicians more adequate compensation for professional service, to insure better quality of medical and surgical care, and to furnish state aid so that the health centers described can be provided, their medical and surgical work can be standardized, through the state supervision, and thus a higher quality of professional service assured. To aid further in securing this end highly qualified visiting consultants are to be made available by the State Department of Health to assist local physicians in diagnosis and treatment of difficult and obscure cases, and modern laboratory facilities of all kinds, auxiliary to the service of the state laboratory are to be provided.

It is confidently believed that this plan is not only practicable and desirable but, also, that some plan of this sort will be absolutely necessary if industrial workers, inhabitants of rural districts, and the great proportion of people of moderate means are to have adequate medical and surgical care which at present they do not receive and can not command. It is further believed that the plan here set forth will improve materially the health of the districts in which it is put into effect, will contribute immeasurably to the public welfare, as well as to economic and industrial prosperity, and that its cost will be insignificant as compared with the benefits to be derived.

It should be emphasized and distinctly understood that physicians rendering service in connection with the big hospitals, clinics, laboratories, and all the health activities involved in the plan should be properly compensated; otherwise the decrease in the number of physicians and deterioration in quality of service which has already been made plainly manifest in some districts will surely continue, greatly to the detriment of the people of the state. It is self-evident that every government owes to its people not only facilities for education, but also physical resources for the prevention of disease and the treatment of sickness adequate to and approximating in quality the high standards which the progress of medical science has made available.

Would Coordinate Agencies

The enactment of this bill and the establishment of such health centres would greatly aid in the coordination of all the public health and public welfare activities of the district; would prevent overlapping of effort, promote economy in administration, and make possible the extension of an efficient health service to every portion of the district.

It would also contribute materially to the improvement and the extension of all health activities and would render them far more effective.

There is a further argument in favor of the enactment of some legislation of this nature,—*viz.*, that the funds for the initiation of this greatly needed work and its support are derived, first, from local community appropriations, and, secondly, from state aid, and their payment for services in proportion to their means by the recipients, and the moneys thus raised are actually spent in very large measure for the work, and only to a very small extent for administration, as has been the case too often in many plans for social betterment.

MEMORANDUM

MEMORANDUM as to the provision of a bill authorizing a county, city, or consolidated health district to create and maintain one or more health centers and providing state aid therefor.

Purposes of the Bill

(1) To provide for the residents of rural districts, for industrial workers, and all others in need of such service, scientific medical and surgical treatment, hospital and dispensary facilities and nursing care, at a cost within their means or, if necessary, free.

(2) To assist the local medical practitioners by providing: (a) Facilities for accurate diagnosis by a coordinated group of specially qualified physicians and surgeons, both for hospital patients and for out-patients. (b) Consultations and advice as to treatment by medical and surgical experts. (c) Clinical, bacteriological, and chemical laboratory service and x-ray facilities at moderate cost or free, when necessary.

(3) To encourage and provide facilities for an annual medical examination to detect physical defects and disease, to discover conditions favorable to the development of disease, and to indicate methods of correcting the same.

(4) To provide or aid in securing adequate school medical inspection and school nursing service, in cooperation with the Department of Education.

(5) To secure or aid in securing better enforcement of the Public Health Law and a more effective administration of Public Health activities within the area served.

(6) To provide a public health nursing service adapted to and adequate for the community served.

(7) To aid in securing the dissemination of information in regard to public health throughout the area served.

(8) To aid in securing adequate compensation for medical and surgical care rendered in hospitals and clinics, in order that efficient service may be everywhere available.

(9) To provide laboratories, group diagnosticians, consultants, and hospital facilities in the smaller cities and rural districts; to counteract the growing tendency of medical practitioners to remove to larger centers, and to attract to and to retain in the practice of medicine in these communities a larger number of qualified practitioners of both sexes.

(10) To provide medical libraries, including books, pamphlets, periodicals, leaflets, exhibits, moving picture films, and kindred educational facilities, with halls for meetings if needed.

(11) To provide hospital and other necessary resources for dealing promptly with epidemics.

(12) To reduce illness and disability among the industrial workers of the state by providing prompt and accurate diagnosis and efficient treatment for sick and injured workers and the members of their families.

(13) To coordinate public health activities within the districts.

Health Centers Provided

(1) A health center may consist of the following parts, any one or more of which parts may be established at one time with the approval of the State Commissioner of Health and the formulation of a general plan for the whole center.

(a) *Hospitals.*—The erection of new hospitals or arrangements with other institutions, or both, so that they shall form essential parts of the center. Such hospitals may include as units thereof existing or hereafter established hospitals or pavilions for the care of tuberculosis, for cases of other communicable disease, for children, for cases of maternity and mental diseases, and for other groups. Existing tuberculosis hospitals may become parts of the health center of a city or county by which they may have been established.

(b) *Clinics for Out Patients.*—These would include especially those now regarded as public health clinics, such as those for tuberculosis and venereal disease, prenatal and child welfare, mental and nervous diseases and defects, and clinics for school children, dental clinics, and also medical, surgical, and diagnostic clinics.

(c) *Laboratories.*—Clinical, bacteriological, and chemical laboratories, auxiliary to the state laboratory, and x-ray laboratories would provide services at moderate charges, or free, affording modern laboratory facilities needed in the diagnosis and treatment of disease.

(d) *District Health Service*, with a district health officer and deputy health officers in various parts of the district, such districts to be either a city or county, or a consolidation of two or more existing health districts (such consolidation to be approved by the State Commissioner of Health). The present health officers in these districts shall act as deputies during their present terms of office. In the subsequent appointments of deputies in the various portions of the districts, persons residing therein possessing the qualifications prescribed by the Public Health Council shall have preference. Each local health board shall appoint for its own town or village a deputy to the health officer of the health center district.

(e) *Public Health Nursing* service for all parts of the district.

(f) *Center for School Medical Inspection.*—Proper medical supervision and facilities to enable practitioners to provide adequate treatment for all school children showing physical defects or disease.

(g) *Headquarters.*—All health, medical, nursing, and other public welfare activities of the district which wish to utilize the center could make it their headquarters.

(2) The locations, sites, plans and initial equipment of the health center shall be subject to the approval of the State Department of Health. The State Department of Health and the State Architect shall provide model plans for such centers for any community requesting them.

State Aid to Health Centers

(1) To be granted for each hospital bed constructed or provided for under this statute. (a) For new construction and equipment of hospitals, one-half of the cost to be paid by the state, such payment not to exceed $750 per bed; and beds for the purpose of this provision to be in proportion not in excess of one to each five hundred of the population. (b) A grant of seventy-five cents per day for every free patient maintained in any hospital operated as a part of a health center.

(2) To be granted for clinics and annual medical examinations. (a) A grant for the creation of out-patient clinics equal to one-half of the initial cost of establishment, the amount to be paid by the state for this purpose not to exceed $5,000 per clinic, and twenty cents for each free patient in such clinic; one such center for each district, provided that in counties or cities or districts having more than 50,000 population there shall be not more than one health center per 50,000 inhabitants or major fraction thereof. (b) A grant of fifty cents for each free comprehensive annual medical examination made at the health center.

(3) *For the maintenance of laboratories*, a grant from the state of one-half of the annual cost of maintenance of laboratory of health center, the sum to be paid by the state not to exceed $3,000 per annum for each laboratory, and $1,500 toward the initial installation and equipment of such laboratory.

(4) *For salaries of deputy health officers*, a grant of ten cents *per capita per annum* toward the salaries of deputy health officers in health districts having less than 1,500 population, and of five cents *per capita per annum* in health districts having a popualtion between 1,500 and 3,000, in addition to such salaries as they are entitled to receive from the local treasury.

(5) The total annual grants for the construction of hospitals and clinics shall not be in excess of $2,000,000; and for the maintenance and operation not in excess of $2,000,000. Salaries and traveling expenses of consultants and experts employed by the State Department of Health, and other expenses necessarily incurred by the State Department of Health in the enforcement of this Law, shall be paid from the sum appropriated for grants toward maintenance and operation of health centers—this sum not to exceed $250,000 *per annum.*

General Provisions

The District Health Officer may be the superintendent of the hospital and general director of health of the district and of the hospital and medical activities connected therewith. The qualifications for district health officers, deputy health officers, superintendents of hospitals and medical activities, chiefs of clinics, and other medical officials and nurses shall be fixed by the Public Health Council, and their appointments be subject to the regulations of the State Civil Service Commission.

The work of all health centers, hospitals, clinics, and district laboratories connected therewith shall be inspected and standardized by the State Department of Health, and the state grants shall be paid only on the written approval of the State Commissioner of Health.

Provision shall be made for occasional or periodic consultations or clinics at the health centers by specialists in medicine and surgery to be furnished through tho State Department of Health, and wide previous public announcement of these clinics and consultations shall be made. At these consultations and clinics health officers and physicians may bring their patients for assistance in diagnosis and for advice as to treatment. Fees received from these consultations for the state service shall be credited to the hospital or center where the service is rendered.

The health center laboratories shall be under the supervision of the director of the State Health Department Laboratories, in order that their work may be maintained at a high level of efficiency; and the facilities of the state laboratory service shall be available to supplement those of the laboratories of the health centers.

The salaries of the medical and surgical staff, the fees for medical and surgical care, and the conditions for free service in the hospitals and clinics, shall be determined by the Board of Managers. The method of appointment and composition of such boards of managers of the health centers and hospitals to be provided for in this bill.

THE LANGE COLLOIDAL GOLD REACTION

IN 1912 Lange first presented the colloidal gold reaction. Since then the test has been applied by an increasingly large number of laboratory investigators until at the present time it has become a routine part of spinal fluid examination in any well regulated clinical laboratory. However, even after these eight years of trial there still remain points of discussion both regarding the technical application of the test and the clinical interpretation of the results of the test. Warwick and Nixon[1] present a complete study of the reaction and a review of the literature bearing on it. Their work represents the results of an analysis of 800 spinal fluids from 408 patients and a review of some fifty-eight articles in the medical literature. Like previous investigators, Warwick and Nixon lay great stress on the preparation of a satisfactory solution, and say that once a satisfactory solution is obtained it appears to be very stable and, if kept corked in a dark cupboard, will remain satisfactory for months. Anyone wishing to try out the test should read the technical portion of this article because of its valuable review of various modifications of technic proposed as well as the careful description of their own method.

A positive reaction, if present at all, begins to appear immediately and is complete in from eight to twelve hours. All syphilitic curves appear the same at first, with the typical paretic curve developing later. These curves are complete only after twelve hours. On the other hand, the test showing no beginning color changes at the end of one-half hour may as well be discarded, as none will appear later. They use the usual methods of charting their reaction.

Clinical interpretation of their results was based on the grouping of cases under seven divisions: (1) *dementia paralytica*, (2) *tabes dorsalis*, (3) cerebrospinal syphilis, (4) multiple sclerosis, (5) cord and brain tumors, (6) meningitis, and (7) miscellaneous group. In *dementia paralytica* the typical curve was obtained in 94.5 per cent of cases, which was higher than the globulin tests, the cell count, or the cerebrospinal fluid Wassermann. In their series only one non-syphilitic case, other than multiple sclerosis, gave a typical paretic curve and that was a case of brain abscess subsequently verified by operation. "Of the spinal fluid reactions in *tabes dorsalis*, the colloidal gold is definitely the most valuable," being positive in 74 per cent of the cases as against 53 per cent Wassermann, 46 per cent cell count and 44 per cent globulin. In nine instances it was positive when the other tests were negative. In several patients given provocative treatment the colloidal gold reactions were found to be the first to become positive. In cerebrospinal

1. Warwick, Margaret, and Nixon, Charles E.: A study of the Colloidal Gold Reaction and Its Clinical Interpretation, Arch. Int. Med, xxv:119, Feb. 1920.

syphilis there is an even greater disproportion of colloidal gold tests over the other cerebrospinal fluid tests. In multiple sclerosis the test simulates in its results that found in paresis, but in the experiments of the authors the curve was more frequently in the second zone. In their brain and spinal cord tumors they believe that a curve in the third zone, especially unaccompanied by meningitic symptoms, is of diagnostic value as indicating meningeal irritation, as shown in tumors of the brain or spinal cord; and of their fourteen cases verified by operation or necropsy, such a curve was present in eight cases. This was of special value when found in these conditions accompanied by negative or faintly positive globulin tests and a low cell count, because meningitis, which has a similar Lange curve, is accompanied by a markedly positive globulin test and a high cell count.

In treated cases they found that the spinal fluids gave little or no indication of change of reaction, while the patient showed marked clinical evidence of improvement. This justifies the assumption that the colloidal gold curve, while of very definite value in initial diagnosis, is very often practically useless in treated cases, either for diagnosis or prognosis, and has been found not to parallel clinical symptoms. One patient who was receiving intensive treatment gave practically the same colloidal gold curve for three years.

The summary which the authors make of their rather elaborate study includes the following:

The colloidal gold test is the most delicate of the routine spinal fluid reactions.

It does not replace any other test, but on the other hand is of independent value and is of special value in early diagnosis of neurosyphilis.

The various curves are not specific.

Patients with no involvement of the central nervous system or who are non-syphilitic give no colloidal gold curve.

Clear cut clinical cases of *tabes dorsalis* may show all the spinal fluid reactions negative both before and after treatment.

Other conclusions have already been discussed in the body of this review.

Kellert's[2] article gives the experience of the Bender Hygienic Laboratory in Albany, New York, for the past four years, and it is the chief object of this paper to record the few instances of false reaction. In their negative tests embracing seventy-five fluids from a variety of conditions there were three which gave positive Wassermann reactions and two from patients whose blood yielded positive Wassermann reactions. In his syphilitic cases fairly constant reactions were obtained, although he claims that in 22 per cent of the fluids the curves could not be interpreted, being either slight or irregularly exaggerated. He believes that the method is more sensitive than the Wassermann test, but that there is much greater possibility of error. [The editor notes that Kellert makes no attempt to differentiate by the test paresis, tabes, and cerebrospinal syphilis. This, he believes, may account for some of the difficulty of interpretation. Furthermore, no mention is made of multiple sclerosis, which, as has been shown by Warwick and Nixon, may give marked syphilitic curves.] In their tuberculous fluids, forty in which the tentative clinical diagnosis of tuberculous meningitis was made gave positive colloidal gold curves. Subsequently, seven of these were excluded as non-tuberculous. Twenty-seven cases of acute meningitis were examined and 74 per cent gave curves suggesting acute meningitis. On the whole, they found the reaction confirmatory of the clinical diagnosis in approximately 80 per cent of the cases. It apparently is most valuable in cerebrospinal syphilis.

Like Warwick and Nixon, he believes the colloidal gold reaction is valuable as an additional or confirmatory test; that its greatest value is in the syphilitic diseases of the central nervous system; and that it may serve to differentiate between tuberculous and other forms of meningitis. He emphasises that cerebrospinal fluid contaminated with blood in small quantity frequently gives luetic reactions and that positive results unconfirmed by other tests are of only slight value. Unlike Warwick and Nixon, he believes that the Wassermann reaction and the cytological examination of the spinal fluid are of greater value than the colloidal gold test.

ACUTE EMPYEMA—A BRIEF REVIEW OF RECENT DEVELOPMENTS

THE huge incidence of empyema following pulmonary diseases in the epidemics of the last few years, the high mortality have stimulated a large amount of investigation of the etiology and treatment of this complication. Many of our former views have undergone modification or a complete change.

Graham and Bell[1] were the first to overthrow our conceptions or misconceptions of intrathoracic pressure. We knew that the mediastinum is not a rigid wall separating the two pleural cavities, but it remained for them to show how mobile a structure it really is and how readily it responds to any change of pressure in either of the cavities. They believe that any change of pressure on one side will immediately, provided no adhesions are present, be transmitted to the other side as well. An open pneumothorax on one side

1. Graham and Bell: Am. Jour. Med. Sc., December, 1918.

means an equal change of pressure on the other and a corresponding collapse of the so-called sound lung. The amount of collapse of the lung in an open pneumothorax varies proportionately as the size of the actual opening in the chest wall compares to the size of the trachea. They have evolved a mathematical formula for the largest actual opening in the chest wall possible without death. The size of this opening varies according to the vital air capacity of the patient. When the vital air capacity is greatly diminished as in penumonia, for example, the size of the opening which can be made is greatly reduced.

These facts explain the results found clinically in practically all the camps; namely, that a patient whose breathing space is already diminished as a result of his pulmonary infection can not withstand the additional burden of an open pneumothorax. As the pneumonia clears up and his vital air capacity increases, the patient becomes more and more able to compensate the interference with respiration resulting from a pneumothorax. After adhesions have formed, which tend to stabilize the mediastinum, the dangers from a thoracotomy are reduced to a minimum.

The etiology of empyema is a mooted question. Some observers believe that there is a hemotogenous infection of the visceral or parietal pleura, resulting first in an exudative pleurisy and then in empyema; others maintain that there is a direct extension from the involved lung tissues into the visceral pleura. Moschcowitz[2] in a recent article claims to have found evidence at autopsy confirming the theory that empyema follows rupture of a small subpleural pus pocket in the lung through the visceral pleura directly into the pleural cavity.

The progression of events, at any rate, is (1) a pleurisy, (2) a serous or a serosanguinous fluid —which in many of the severe cases developed with remarkable rapidity—a gradual increase in this fluid of bacteria and cellular elements, and, (3) finally, provided the patient lives long enough, the development of frank pus.

Clinically, the aspect varied greatly according to the type of bacteria found and according to the strain of the organism. The streptococcal empyemas following the influenzal infections were extremely fulminant; the pneumococcal empyemas were much more benign. In all the epidemics the virulence of the organism seemed to diminish so that, towards the end, even the streptococcal empyemas offered a more favorable prognosis. Miller[3] feels that were we to go through another epidemic similar to the kind we had at the various army camps, with our present knowledge of treatment our mortality rate might be very much the same.

As regards the diagnosis of effusion, all writers are unanimous in proclaiming that the usual physical signs of impairment of percussion, diminution or absence of tactile and vocal fremitus, and absence of breath sounds, alone can not be relied upon. The x-ray has proved a most valuable assistant. Exploratory aspirations are indispensable. Gray[4] suggests that the best way to make an early diagnosis of effusion is to suspect every pneumonia guilty unless proved innocent.

At the beginning of the epidemic of the winter 1917-1918 cases were operated early, as had been the custom heretofore. In some camps operation was performed as soon as the fluid was discovered, in others as soon as the fluid was found to contain bacteria. The usual type of operation was rib resection and the usual outcome was death. It soon became apparent that this procedure was radically wrong. It was evident that a toxic patient, fighting for air, could not withstand the shock of an open pneumothorax. Gradually reports showing improved results by delaying operation, convinced us of our error, and brought about a change of procedure. The mortality became lower, the Empyema Commission[5] published its monumental work and we gradually arrived at our present conceptions. The Empyema Commission advocated early and repeated aspirations. It advocated drainage without the shock of a wide open pneumothorax. If the fluid became frank pus, a rib resection was recommended, adhesions having been formed by this time. As after-treatment the Commission advocated, along with the usual hygiene, exercises and the use of a blow-bottle or some other device to help expand the collapsed lung. Bartlett[6] makes the practical suggestion of connecting a mercury manometer, such as used in blood pressure machines, for example, to the blow apparatus, thus stimulating the patient's interest by allowing him to observe any improvement.

Aspiration is performed with the usual needles. Suction is induced by means of a pump, a faucet-suction apparatus, a vacuum created in a bottle by means of combustion or syphonage. For small quantities of fluid a large glass syringe will prove to be the simplest and most efficacious instrument. Aspiration is a diagnostic procedure and as such is indicated whenever the presence of fluid is suspected. The presence of the fluid established, aspiration is indicated to relieve re-

spiratory or cardiac distress, pain, a rise in temperature or continuance of fever, whenever these are due to the effusion. Aspiration should be repeated as often as these indications arise. If the fluid re-accumulates rapidly continuous drainage should be resorted to, by means of Diedrich's[7] or similar methods. By the time the fluid has become frank pus adhesions will have formed, so that a more radical procedure such as rib resection can be undertaken.

Following the publication of the good results obtained simply by repeated aspirations, Diedrich, Wright, and others brought forward methods for continuous drainage of the chest without producing an open pneumothorax. In the Diedrich method the chest wall is pierced between the ribs by means of a trocar; a small rubber tube is inserted through a lateral opening into the sheath of the trocar after the obturator has been withdrawn. The trocar is now withdrawn, leaving the tube in the chest wall. The tube can be connected to a negative pressure apparatus, or simply attached to a long rubber hosing which is allowed to hang over the side of the bed, the end being submerged in a bottle of water. The chest is irrigated and flushed out through the tube. Good results have been reported by using Dakin's solution to irrigate, and also to inject a quantity of Dakin's solution at two-hourly intervals, the amount injected not to be more than 100 cc., or, in small cavities, about one-half or one-third the contents of the cavity.

One of the requisites of the Carrel-Dakin treatment was "pooling." The solution was not to drain off immediately but was permitted to form a pool to allow the solution to remain in longer contact with the infected tissue. For this reason many of the advocates of the intra-thoracic Carrel-Dakin method advised a small chest opening, plugging this opening with gauze. This in itself, in the light of subsequent research, would account for the marked success of this method. Stewart,[8] working in New York at the Rockefeller War Hospital, treated his cases along the following lines. A small incision was made through the chest wall, with or without rib resection. Through this incision several Dakin tubes were inserted, each tube threaded on a silver wire, gauge 24-27, which was of sufficient plasticity to retain its shape, and then spread the tubes fan like over the entire interior of the cavity. In this manner fluid, when injected, came into contact with every portion of the cavity wall. The chest was irrigated until the fluid returned clear. A gauze damming was placed around the tubes, and the skin protected with vaselin strips in the usual manner. Dakin's solution was injected every two hours, the amount being about 100 cc., or, in a small cavity, about one-half to one-third the contents of the cavity. The dressings were changed every twenty-four hours, the tubes tested and changed if necessary. During the dressing while the cavity was irrigated the position of the patient was changed so as to facilitate a thorough flushing. The cases were controlled by means of bacterial counts, and when the "sterile" stage was reached—one organism to every five fields—the opening was closed by secondary suture.

If frank pus developed adhesions could be surmised and an open pneumothorax made with little fear of producing shock.

In these cases the consensus of opinion favors a large opening, a resection of a part of one or more ribs. The opening should be made whenever possible in the most dependent portion of the empyema cavity. The Carrel-Daken treatment here has according to most authors given brilliant results.

One of the arguments in favor of an intercostal thoracotomy as against rib resection, is that no osteomyelitis develops from cut surfaces of bone. In many instances this osteomyelitis is the cause of prolonged drainage and sinus formation. Stevens[9] claims that recurrences are more apt to occur if a chest is allowed to close while cavities containing air still remain. Others[10] do not agree with this, provided the cavity has once become sterile. Premature closure of the chest wall by secondary suture usually leads to a reopening and a continuance of the drainage. There is a possibility of multiple cavities.

A word as regards the anesthetic. Local anesthesia has been found to be the anesthetic of choice. The anatomy of the chest wall lends itself well to this method. The intercostal nerves are easily blocked. Some surgeons prefer to block the nerves near their origin from the spine while others block nearer the site of operation. For larger procedures it is advisable to block the intercostal space above and the intercostal space below the spaces in which the operation takes place. For thoracotomy without rib resection simple regional infiltration is the most satisfactory method. Very little anesthetic is required. A well administered local anesthesia, together with careful gentle operative technic, will suffice in practically every case of acute empyema. General anesthesia is poorly tolerated.

THE AUTONOMIC NERVOUS SYSTEM AND DISORDERS OF THE STOMACH

By HOMER WHEELON, A.M., M.D., and J. EARL THOMAS, M.D., Department of Medicine, Bethesda Hospital, St. Louis, Mo.

STATEMENTS relative to the functions of the stomach either in health or disease should be made with hesitancy. Previously accepted theories are gradually giving way to new data. Conflicting evidence relative to the stomach fails to grow less. The physiologist, gastrologist, endocrinologist, and radiologist are still at variance with one another. Apparently the only thing in common among this group of workers is the stomach itself. No doubt the observations made upon the functions of the stomach by various means are correct for those particular modes of procedure. To a great extent interpretations are influenced by the "personal equation," hence data are open to explanations from different points of view. The theories of Pavlov[1] have gradually diminished in importance. The theory of "the acid control of the pylorus" as evolved by Cannon[2] at present is not sufficiently strong to withstand the more modern tests of the physiologist and the clinician. Just now the organs of internal secretion, plus or minus their normal function, are being heralded as the cause of normal and abnormal cell functioning. Truly, experimentation and observations have far outstripped evaluation and coordination, at least, in so far as concerns the data upon the function of the stomach. With so much confusion still existing as to the normal function of the stomach it is no wonder that functional pathology makes but little progress.

A Correlation of Observations

It is not the purpose of this article to offer new methods of study or to attempt the evolution of a new theory. A correlation of certain observations, however, seems to be of sufficient interest to warrant discussion. When it is considered that the symptoms, signs, and indications of disease represent deviations from the normal, the need of a more sound understanding of the normal functioning of organs becomes apparent.

It is necessary to determine three factors in order that the function of an organ be properly understood: (1) The properties of the physiological unit of the organ, namely, the cell; (2) the nutritional factors related to the cell; and (3) the influence of nerves upon the nutrient channels and the organ as a whole.

Normally, muscles respond best to nerve impulses delivered to them from the central nervous system. However, experimental evidence has shown that muscle cells of all types possess independent irritability and contractility; hence motility, as demonstrated by muscle, must be considered a myogenic property. It, therefore, follows that the nerves are supplied to contractile tissue for the purpose of controlling the degree of their action, that is, the nerves influence a regulatory power over muscular activities. The higher the degree of muscle development the more dependent upon the nervous system these cells become for coordination and sequence of movement.

Nerve Impulses and Secretion

It is still a disputed question as to whether or not secretory cells depend upon the reception of nerve impulses to demonstrate their characteristic properties. On theoretical grounds it would seem justifiable to assume that secretory cells manifest their peculiar functions because of their structure and high degree of differentiation, the nerves acting, as in the case of muscle, only as regulators of function. Granting that secretory cells do go into action only upon the reception of nerve impulses, there are still to be considered the vascular changes which make possible the delivery of fluid material to the gland. Secretory glands in an active state demand an increased supply of blood, and this increase in supply can only be delivered because of changes in the vascular apparatus. Such vascular changes are directly under the control of the autonomic nerves, the augmentors and inhibitors of the vasomotor system. With these points in mind the normal function of the stomach may be considered the result of intrinsic properties of motility and secretion of gastric cells, vasomotor changes sufficient to supply nutrition to and elimination from the cells, and a properly balanced nerve supply. Hence organic disturbances of any one of these factors will of necessity bring about alterations in the mass action of the stomach.

The stomach is innervated with fibers from two sources, the bulbar autonomics coursing by way of the vagus nerves, and the sympathetics by way of the splanchnic nerves. These fibers may be classed as extrinsic nerves to the stomach; they are known to carry afferent fibers to and afferent fibers from the stomach.[1 3 5 23 41]

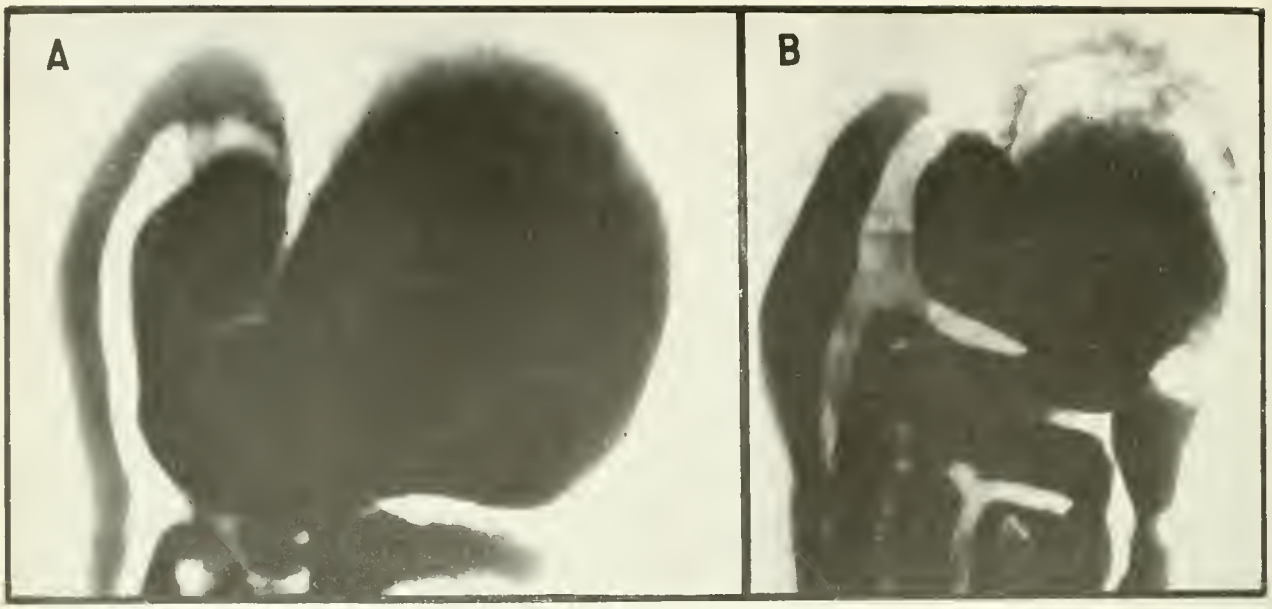

Fig. I. Radiogram of the stomach and small intestine of the dog.
A. Radiogram taken twenty minutes after a barium meal.
Note size and position of the stomach and the degree of transit of material through the duodenum.
B. Radiogram showing the effects of adrenalin upon the tonicity of the stomach and small intestine at a time when the vagus was being excited. Taken immediately following Fig. II C.

Experimentation has shown quite conclusively that, in general, the fibers received by the stomach from the vagus are excitors to motion.[5 41 47] Stimulation of the peripheral end of the vagus nerve may exercise varying effects on the stomach wall and on its sphincters, depending upon the type of organism studied. In the normal animal stimulation of the peripheral end of the severed vagus, as a rule, causes strong contractions of the esophagus as well as of the cardiac end of the stomach and sphincter. After the administration of small amounts of atropin stimulation of the same nerve will occasion inhibition of the esophagus and dilation of the cardiac sphincter.[15 24 26 27 39] On both cardiac and pyloric portions of the stomach the vagus exercises inhibitory as well as augmentory effects.[27 35] So far as concerns the musculature of the fundus or body of the stomach, the most usual effect is an inhibition during stimulation of the vagus succeeded by an augmentation of tonicity following the removal of the stimulus. If the vagus is excited a number of times the tonus of the muscular wall augments with each stimulus. Stimulation of the vagus also causes inhibition of the pylorus, followed by contractions.* This inhibition, however, may be very short and in certain cases absent, so that during the excitation the inhibition is followed by a series of large rhythmic contractions.[27] The prevailing motor effect of the vagus, therefore, is an augmentation of tone of the musculature of the stomach and an increased peristalsis in the pyloric portions. (Figs. I and II.)

The sympathetic fibers coming through the splanchnics are usually considered as inhibitors to the stomach, especially in the higher forms. When stimulated, they bring about a reduction in the tonus and contractile power of the stomach and possibly an inhibition of the pyloric sphincter. In certain forms the sympathetics, when stimulated, cause marked contractions to occur in the pyloric and prepyloric portion of the stomach, hence the motor supply of the stomach as a whole may vary in different animals.[5 7 8 9 12 29 35 37 40 49 50]

Stomach Essentially Autonomic

It appears that the orderly movements of the stomach are merely regulated by the opposing set of nerves, the stomach itself being essentially an autonomic organ. The excised stomach, when kept in warm saline solution, executes regular movements which, if not identical with those observed under normal conditions, have at least an orderly sequence.[5 18] Also, gastric digestion may proceed quite normally both as regards secretions and movements following section of the extrinsic nerves. Severance of the vagi alone results in the abeyance of gastric action for some time, and when peristalsis reappears the contractions are at first shallow. However, after digestion is well started the vagus nerves can be severed without altering either the nature of gastric peristalsis or the rate at which food leaves the

*Certain observations soon to be reported indicate that the primary response of the pylorus to effectual stimulation of the vagus below the heart is a strong contraction. This is followed by an inhibition (loss of tone) of short duration after which tone is built up to the normal by a series of powerful rhythmic contractions.

stomach.[5] Gastric tonus once established at the beginning of gastric digestion is self supporting and, like the "psychic secretions," as shown by Pavlov, maintains itself because of local mechanisms. However, following the primary loss of tone because of severance of the vagi, intrinsic mechanisms are sufficient to build up a compensating tone strong enough to render the stomach so contracted that the reception of only a small amount of food is required to set up active peristalsis. The inhibitory impulses delivered to the stomach by way of the vagi appear to exert their influence only when gastric tonus (vagus excitation) has developed a considerable pressure in the stomach. Hence, a high degree of gastric tonicity may be reduced because of inhibitory impulses from the vagus sufficiently great to accommodate the presence of new food delivered to the stomach by way of the esophagus.[5] If the vagi are cut, this phenomenon fails to take place. On the other hand Elliot demonstrated that the administration of adrenalin resulted in a maximal loss of gastric tone and peristalsis.[1-] (Figs. II-B and IV-B.) The same phenomenon occurs following direct stimulation of the sympathetics to the stomach. It may, therefore, be concluded that the sympathetics act as inhibitors of gastric tone and peristalsis. Probably these nerves exert a constant influence for the reason that gastric peristalsis and the rate at which the stomach empties are more nearly normal when all of the extrinsic nerves of the stomach are severed, than when the vagi are cut and the splanchnics left intact.[5] The work of Kuntz adds weight to this contention. He concludes from his histological studies that the normal control of the digestive functions is exercised primarily by local reflex arcs. The general control exercised by extrinsic nerves is largely tonic in character.[2] (Fig. 1.)

Gastric activities are much less dependent upon the control of the central nervous system than, for instance, those of the esophagus. Indeed, they are better marked when the extrinsic nerves are severed. The presence of food in the stomach is sufficient to excite gastric action when other than local reflex action has been excluded.[1 18 33] As Dixon has shown, cessation of orderly movements of the stomach is only to be accomplished following complete paralysis of both the intrinsic and extrinsic nerves. Therefore, *the stomach may be regarded as an autonomic organ influenced to cooperative activity because of the intergrative action of the central nervous system acting through the vagus and splanchnic nerves.*

The Central Nervous System

Through the action of the extrinsic nerves the stomach may be influenced favorably or unfavorably by conditions directly or indirectly affecting the central nervous system. Wertheimer[50] has shown that stimulation of the central end of the severed sciatic or vagus nerve may cause reflex inhibition of the tonus of the stomach, this being due, as he believes, to an excitation of the sympathetic centers.

Doyon[10] confirmed the results of Wertheimer in cases in which the movements and tonicity of the stomach were first increased by the action of pilocarpin and strychnin. Stimulation of the central end of an afferent path may also give rise to inhibition of gastric movements because of reflex stimulation of inhibitory fibers in the vagus.[50] Cannon[5] has shown that all movements of the stomach cease as soon as experimental animals show signs of anxiety, rage, or distress, condi-

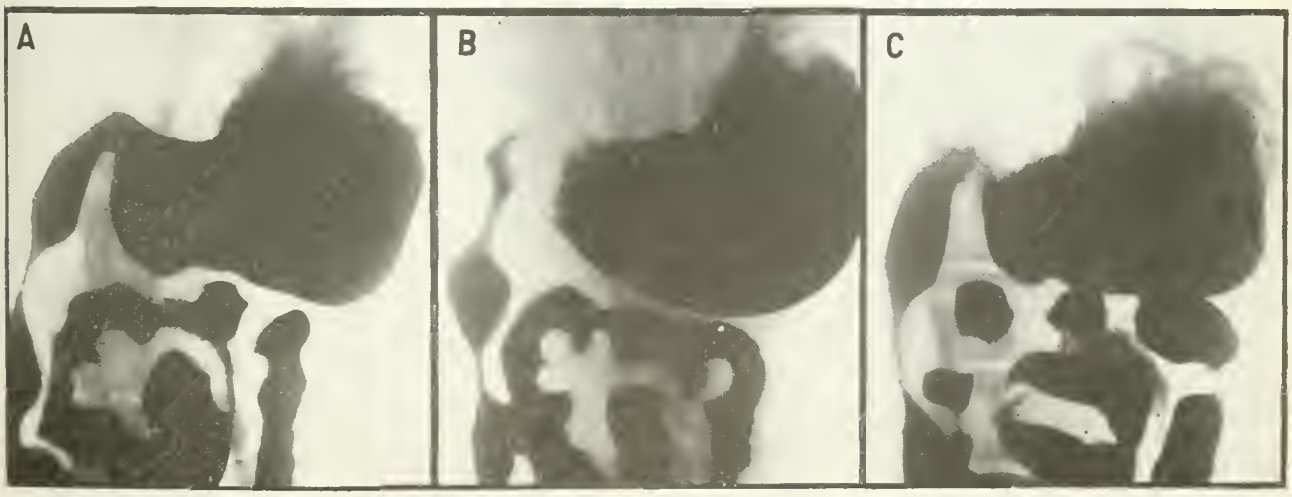

Fig. II. Radiograms of the stomach and small intestine of the dog during stimulation of the vagus nerve.
Note degree of tonicity in stomach and segmentation of small intestine; also, the degree of activity of the pylorus and duodenum. The great diminution in the size of the stomach is the result of active gastric motility during vagus stimulation. Figs. II and III are from the same animal.

tions which are equivalent to sympathetic nervous activity. Psychic states, trauma, asphyxia, and vascular changes also may indirectly influence the processes of gastric digestion. May,[35] for instance, believes that any effect produced by stimulation of the splanchnic nerves is probably due to the simultaneous influence on the vascular supply of the organ; the blood vessels being constricted, an artificial anemia is produced which in itself is sufficient to account for diminished activity. More recently Smith[46] has shown that strips of the stomach (cat and human) may show relaxation following the application of adrenalin, or relaxation of some parts and constriction of others (guinea-pig, rabbit, and dog). The reaction of the sphincters to epinephrin was always that of contraction. The latter observation is in accord with the theory of sphincter innervation as evolved by Gaskell[14] from the embryological standpoint. More definite information concerning the nervous control of the pylorus is greatly to be desired.

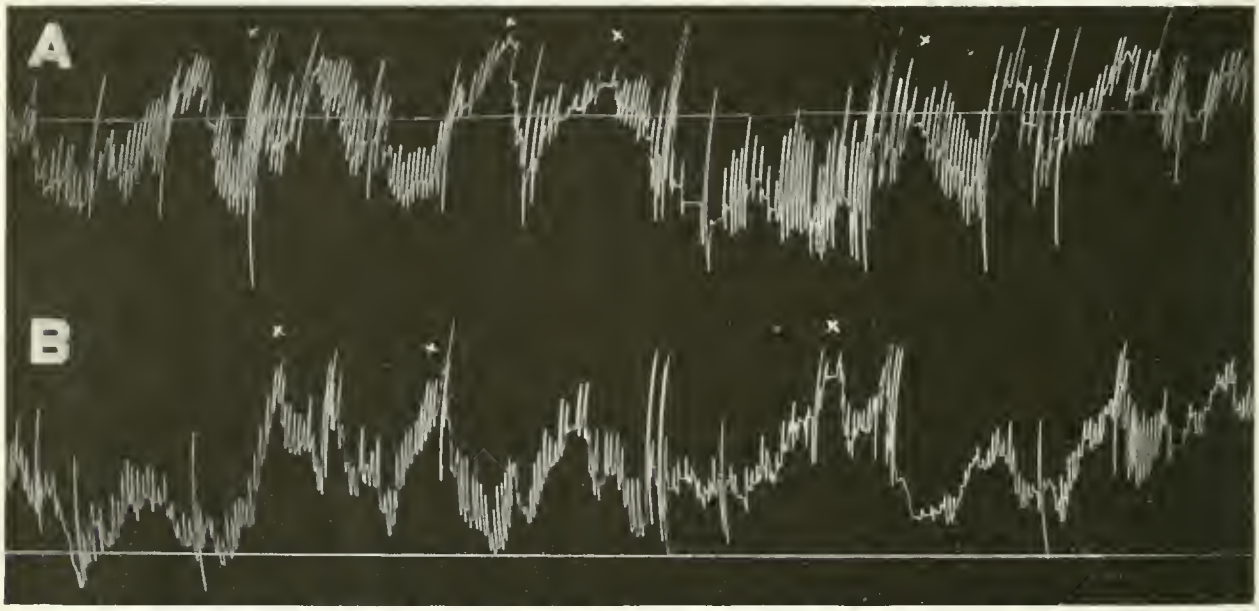

Fig. III Graphic record, ballon method, of stomach contractions of patient suffering from hyperthyroidism.
A.—Tracing made one and one-half hours after the noon meal.
B. Tracing made one hour later, following the ingestion of a cup of cocoa.
Note that the type of contractions are the same in each case and that the degree of tonicity varies greatly. Radiographic examination demonstrated heavy peristalsis and marked changes in tonicity. There were no structural changes. Points marked x appeared synchronous with pain in the stomach.

Muscular Action and Secretion

Influences that alter the action of gastric musculature also affect the function of the gastric secretory cells. Carlson[6] has shown that these cells are continuously secreting but, as Pavlov has shown,[14] the secretion of gastric fluids is greatly augmented because of the reception of nerve impulses over the vagus. On the contrary, excitation of the splanchnics reduces secretory activity, probably as much because of vascular changes as from any direct action upon the glands. If a hungry animal is tempted with the sight of food there is a flow of gastric juice after a latent period of five to seven minutes. Severance of the splanchnics has no effect on this "reflex secretion." However, such a reflex does not occur after division of the vagus nerves below the cardiac branches. Therefore, secretory fibers for the gastric glands run in the vagi. It is also probable that the vagi carry impulses which inhibit gastric secretion. Even following severance of all nerves which connect the central nervous system with the stomach the presence of food in the stomach is sufficient to excite secretory activity. Hence, as Howell[20] suggests, "one must distinguish between *nervous secretion*, due to the action of the secretory fibers in the vagus, and a *chemical secretion*, due to the stimulation of the hormones produced b ythem." The latter type of secretion has been shown by Edkins[11] to follow the injection of decoctions of the pylorus into the circulation, which leads to the conclusion that the gastric glands, while normally under nervous control, are also capable of being locally stimulated through the peripheral ganglia of the gastric wall or the chemical action of the products of digestion absorbed into the blood stream.

If the above physiology is true, then what shall one expect to find as the result of altered functionings of the nervous control of the stomach? Theoretically, an over action of the excitatory fibers of the vagus will lead to an increased activity of the stomach, or a condition of hypermotil-

ity, increased tonicity, and hypersecretion along with gastric spasms. Such a picture is often seen associated with gastric ulcers[22] and just as often no ulcer is demonstrable. Not a few operations for gastric ulcer have been performed upon sufferers of luetic gastric crises. However, gastric ulcers and luetic crises may occur simultaneously; also, gastric ulcers have been sought in cases ultimately found to be suffering from toxic goiter. It follows that the symptoms of gastric ulcer may be present without any indication of organic trouble in the stomach and we must go further back than the ulcer itself and determine what functional alterations antedated the development of the organic disturbance. On physiological grounds the gastric symptoms of ulcer must be considered as due to alterations which favored bacterial invasion at a weakened point.

Are we still justified in considering the etiology of hyperfunction of the stomach, with or without ulcer, to be a "neurosis" of the vagus or the result of an irritating ulcer? If, as indicated, the normal action and quiescence of the stomach are dependent upon the integrity of the organ's nerve supply in conjunction with the secretions and products of other viscera, then any interference with this relationship might be followed by nutritional defects located in the region of greatest anemia or where muscular contractions are excessive.[44] Hence a gastric ulcer probably should be considered as a secondary or incidental lesion, the result of "trophic" changes. On the other hand, gastric spasms and hour-glass contractions possibly should be considered the result of motor responses to definite gastro-intestinal irritation which setting up afferent impulses (vagal) result in cramp-like contractions in the musculature of the stomach and at the same time give rise to localized or diffuse referred pain in the region of the epigastrium.[3 23 30 36 45] Such spasms may be likened somewhat to hunger contractions which, as Carlson[6] has shown, give rise to hunger sensations or symptoms of distress. Irritation of an eroded surface by gastric acid, or tension by adhesions, is sufficient cause to excite painful stimuli from the region of an ulcer. Such visceral pains are conveyed through the vagus and are of the deep pressure sensibility (tension) type allied to Head's[3] protopathic system. Hypermotility and hypersecretion probably always antedate the appearance of an ulcer, but such findings do not necessarily mean that an ulcer is present, for in tabetic crises we find that similar conditions exist, probably because of an involvement of the bulbar autonomic nerves.[25]

Activity of Sympathetic Nerves

Physiologically, an increased activity on the part of the gastric sympathetic nerves would lead to a marked degree of vasoconstriction in the visceral vessels and consequently a reduction in the tonus and motility of the musculature. A spasm or maintained hypertonicity of the arterioles would in time result in an ischemia of the mucosa, which in turn would be followed by superficial necrosis and possibly an ulcer. Such a picture is commonly met with in the clinical association of stasis and hypotonicity of the

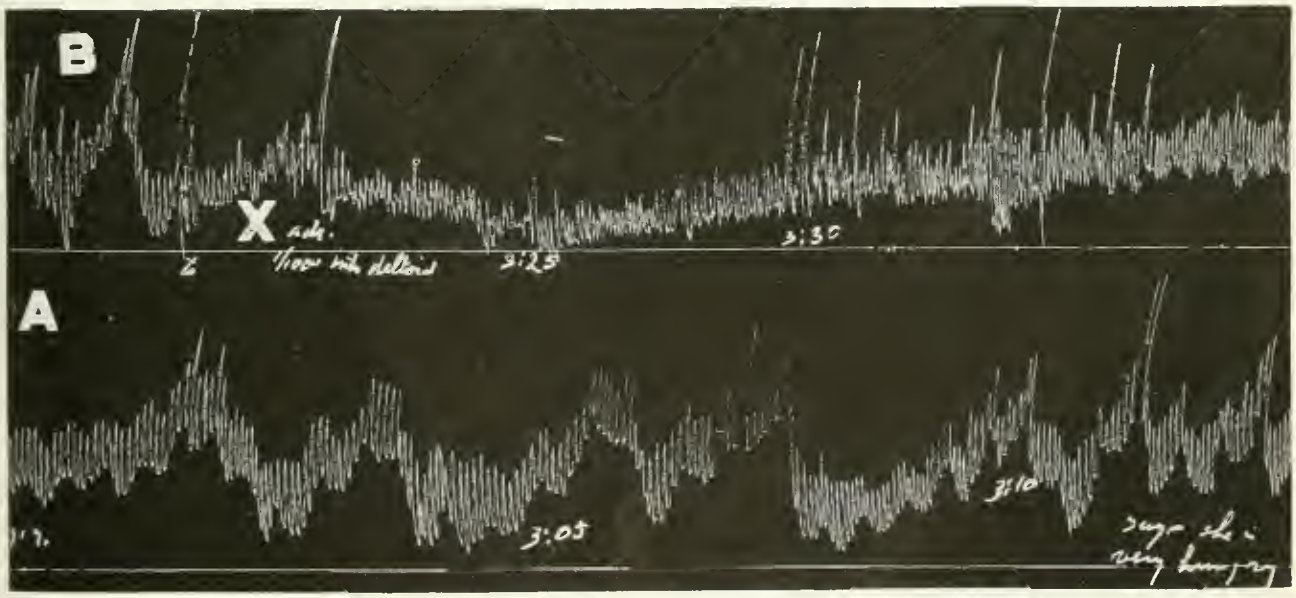

Fig. IV. Graphic record, balloon method, of stomach contractions of patient suffering from vague abdominal pains.
A.—Shows gastric movements four hours after meal.
Note variations in tone and type of contractions. The patient complained of being hungry.
B.—Trace showing the effects upon gastric activity, following the injection of ½ cc., 1-1,000 adrenalin into the deltoid muscle.
Note the drop in tone and cessation of peristalsis. Radiographic examination showed delayed emptying time, increased peristalsis, and adhesions about the descending portion of the duodenum.

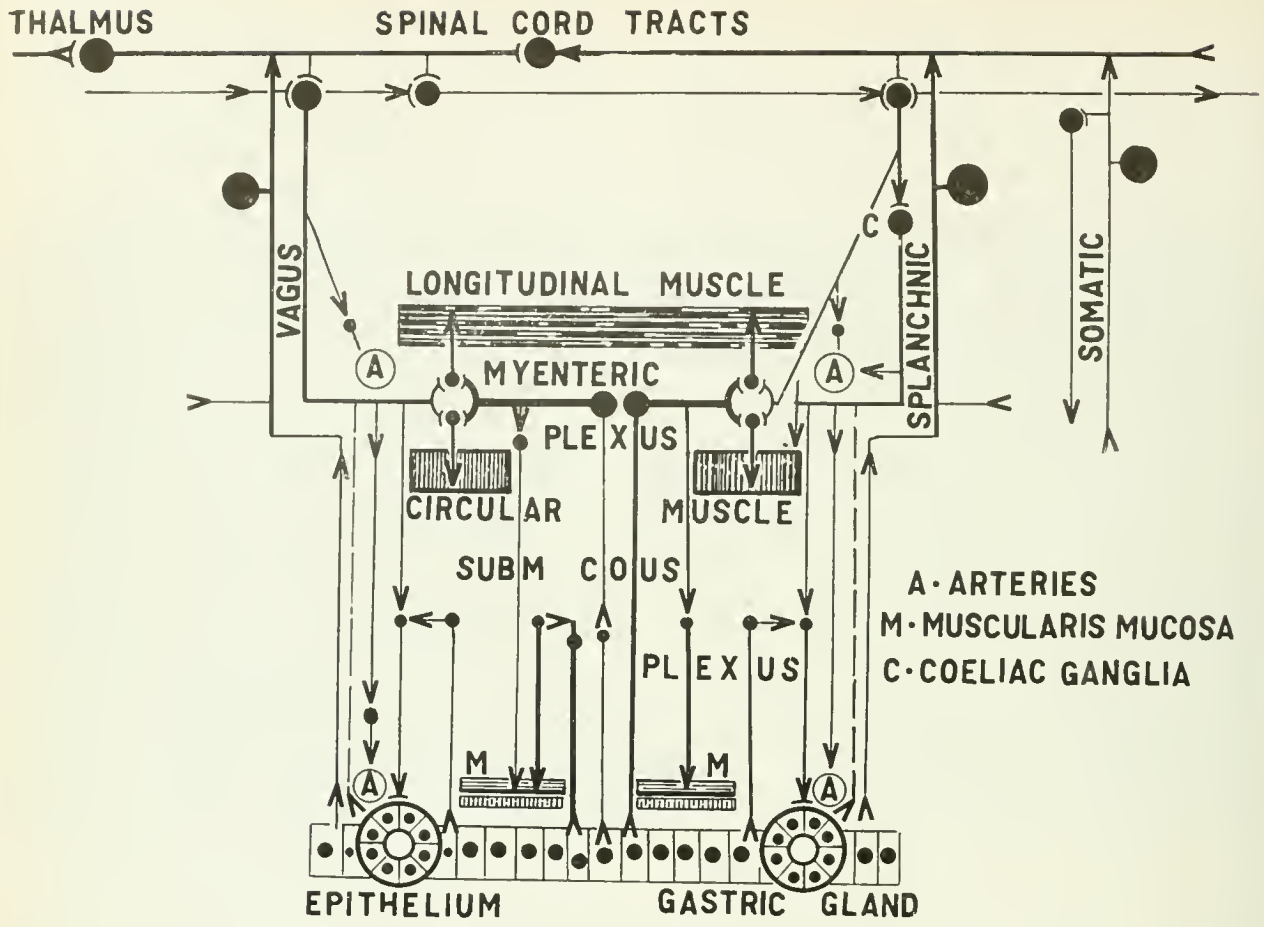

Fig. V. Diagram of the nervous control of the stomach showing myenteric and long reflex paths.

stomach with chronic ulcers or appendicitis. In this case we are forced to attribute the appearance of an ulcer to an overactivity of the sympathetics either because of a hypotonic condition of the vagus or some direct irritation of the true sympathetics. As previously stated, peptic ulcers may be associated with a hypertonic stomach in which the hypertonicity is probably the result of an irritable or unopposed action of the vagus. A spastic contraction of a small area of the stomach musculature, caused by an irritable or irritated vagus, may produce the same condition favorable to a lesion as that due to a spasm of the arterioles (ischemia). In each case the nutrition is impaired.

The Endocrine Glands and the Stomach

Research workers have gradually shown that the internal secretions are powerful regulators of metabolism and that they exert their influence either directly upon cells or influence them indirectly through their nutritional channels thence it becomes necessary to examine the various endocrine functions when altered metabolism or nerve functions occur. As a matter of fact, endocrine disturbances are diagnosed because of altered function on the part of bodily structures, and among such functional alterations those of the stomach stand well in the foreground. However, we would not infer that endocrine disturbances are to be considered as primary etiological factors in all cases of gastric disturbances.

As is well known the action of adrenalin is the same as stimulation of the sympathetic nerves.[42] (Fig. IV.) The thyroid secretion, on the other hand, appears to act upon the parasympathetic nervous system.[42 43 44] Hence, within limits, these two secretions are antagonistic in function. An increase of suprarenal secretion would cause sensitization of the sympathetic fibers which, as far as the stomach is concerned, would result in lessened motility and constriction of the gastric vessels.[17 38] The thyroid secretion, on the contrary, would increase vagus action and bring about increased motility and secretion of the stomach.[25 43 44] Rogers[44] has recently shown that extracts of the thyroid gland acts as vigorous stimulants for the gastric secretion, producing its effects, at least in part, by intensification of the functions performed by the terminal filaments of the gastric vagus. However, extracts prepared from pathological tissue of adenoma-

tous or hyperthyroid human glands are inert. Extracts of the entire adrenal gland actively inhibit gastric secretion and it is therefore presumable that this effect is produced by intensification of the inhibitory function ascribed to the gastric sympathetics. To a less extent extracts of the pituitary gland also inhibit gastric secretion. Hence a normal stomach depends not only upon its own properties to maintain function, but also upon a blood supply, a dual or opposing nerve supply, and a balanced action of the organs of internal secretion.

Exhaustion, fatigue, shock, and stress are known to act strongly upon the sympathetic nervous system and at times to the point of greatly reducing its power to function. The suprarenal and thyroid glands may be reduced to a degree not compatible with normal activity of the viscera. Such conditions would permit an unopposed action of the various divisions of the autonomic nervous system, and such a condition long continued would ultimately result in organic pathology, such as peptic ulcers, appendicitis, constipations, and diarrheas.[32 38] For instance, Mann[24] has shown that dogs dying of adrenal deficiency show gastric ulcer formations in a high percentage of the cases. That such ulcers are not produced by increased acid production may be shown by transplanting pieces of jejunum into the gastric wall in which case adrenalectomy is followed by ulcer formation only in the gastric tissue. However, the works of Stewart and Rogoff[48] lead to the belief that the suprarenal glands and their formation of epinephrin is not indespensable to the animal economy. An overactive gastric vagus may be the result either of sympathetic failure or of conditions which directly irritate or sensitize the vagus centers or the fiber terminals. However, the work of Levy[31] is not in accord with such a belief. It is true that the patients suffering with so-called "hyperthyroidism," do show marked gastric disturbances. (Fig. III.) Acute cases may terminate fatally after a few days of violent and intractable gastro-intestinal crises and profound and progressive cardiac weakness.[15 16]

However, we are not at the present time able to say whether or not the thyroid secretion in these cases represents simply an increased production of the normal secretion or a perverted or toxic secretion.* Notwithstanding these statements, we are beginning to appreciate the fact that thyroid dysfunction is often the result of an exhaustion of the sympathetics. In such a condition the gland is no longer inhibited in its action and consequently attempts to secrete in proportion to the degree of nervous excitation received by way of the vagus[43] and the body is flooded with a superfluous amount of secretion which it cannot utilize with a resultant overactivity on the part of the nerves and organs normally activated by the thyroid hormone. We are, therefore, led to believe that hyperthyroidism and the gastric symptoms associated with it are not to be considered as having their origin in local conditions in all cases, but because of sympathetic failure. Gastric disturbances and ulcers also occur in cases of hypothyroidism. In such cases we may consider the ulcer as having its origin because of vasomotor changes following decreased functioning of the thyroid. The vagus no longer would be activated and the sympathetics, being unopposed, would bring about an increased degree of vasomotor action associated with stasis and hypotonicity of the stomach.

*For an excellent discussion of the function of the thyroid gland see [28].

Ulcer Due to Systemic Disturbances

Gastric ulcers in man show a tendency to spontaneous healing as do also, those produced experimentally in animals. However, disturbances of endocrine glands seem to prevent this natural tendency to heal and, once the ulcer has formed, it tends to become chronic if the constitutional disturbance is not corrected. This point of view necessitates the consideration of peptic ulcer as due to systemic or metabolic disturbances. They cannot, therefore, be cured by surgery alone, although this may remove the mechanical complications and assist in the healing processes.

The diagnosis and physiological understanding of the nervous dyspepsias, the motility and secretory anomalies, changes induced in endocrine disturbances, in all of which sympathetic or psychic influences play a large rôle, are apparently being cleared up on the basis of a proper understanding of the dual innervation supplying visceral organs and the relation of the secretion of the endocrine glands to these same nerves.[21] Observations by means of the x-rays have greatly advanced our knowledge of gastric anomalies and motor disturbances. However, it would seem that x-ray findings must be interpreted as results and not causes. The emotional or psychic factors are probably the true causes, the anomalies representing end results of disturbed function. After years of pathological functioning (symptoms) permanent changes occur, the result of which is a viscious circle in which cause and effect are inextricably interwoven in their symptomatology. At the beginning of such disorders environmental adjustment seems to inflence these cases more effectually than attempted modifications of a preverted nervous system or chem-

ism either by means of active therapeutics or surgery.

It may, therefore, be concluded that the normal stomach is one in which, added to its myogenic properties, a proper reciprocal innervation is maintained associated with a balanced chemism. Alterations in any one of these elements will of necessity break the balance and resulting pathological functioning or symptoms will be in proportion to the degree of severity of the alteration.

SOME MEDICAL TENDENCIES

The address of Dr. Alexander Lambert on "Some Medical Tendencies and Responsibilities," reported in the March issue of the *Journal of the Medical Society of the State of New Jersey*, gives an interesting account of the medical society organized in Paris founded by the Red Cross, which constituted a most successful forum for the exchange of views of the medical corps of the French, English, and American Armies.

At this stage of the war medical and surgical practice was about two years in advance of the literature. Surgical technic, rather than antiseptics was the reliance in infections. Sanitation and preventive inoculation had proved their value.

Dr. Lambert points out the fact that the American school, like the French, is based upon pathology and the experimental work of the laboratory; while the English is characterized by brilliant clinical work.

He regards as a defect in American methods that physiology, the science of normal function, too early in the course gives way to an almost exclusive attention to the morbid processes. One of the great responsibilities of medicine is to turn more toward the development and appreciation of clinical physiology, and to bring it more into the routine of daily practice.

The war accentuated the advantage of medical men working in groups. He takes issue with the view of Mackenzie that only the clinical man is able to look at things broadly, and holds that the best results are attained by men specializing in those branches that really interest them.

Special practice, however, necessitates that men work together—a tendency which has found expression in the greater perfection of present dispensaries. In the development of the dispensary in consultation service Dr. Lambert sees a possible solution to the problem of rendering proper care to all the sick in the community at a cost that would improve the economic status of the people and also of the medical profession.

Dr. Lambert does not overlook the opportunity of the dispensary to broaden and develop post-graduate medical teaching. As only the medical profession can be the judge of adequate service, it becomes the responsibility of the physician to develop and standardize the technical side of all hospitals and dispensaries. It is the responsibility of the medical profession, he says, "to mould their self-reliant individualism into a stronger team work through which, by a greater development of communal sense, they will be more willing to accept the social respnosibilities of their citizenship."

MEDICINE AND INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

Otto P. Geier, M. D., *Editor*

AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

As in many other phases of medical practice, the importance of industrial medicine as a specialty was not appreciated until the field was occupied. Fifteen years ago industrial medical service included little more than the emergency care of injuries. It made no wide appeal as a specialty, nor was its importance to the physician appreciated until the apathy of the profession permitted to be incorporated under Workmen's Compensation such defects of medical administration as must concern the medical profession in general, and the industrial physician in particular.

The development of the concept of industrial medical service from injury repair to a complete medical service, with facilities for group practice and for following up a case with all desired aids, has placed the industrial clinic on a par with that of any other center where scientific standards are enforced, and results and research contribute to the medical arts. The American Medical Association endorsed the new specialty by creating at the 1919 conference a special section devoted to industrial surgery.

The American Association of Industrial Physicians and Surgeons will hold their Fifth Annual Convention in New Orleans Monday and Tuesday, April 26 and 27, 1920. The headquarters and meeting place of this Association will be at the Hotel Gruenwald. This Association has grown to approximately seven hundred members. The attendance is always large. The Atlantic City meeting demonstrated that one day is entirely too short for the reading and the intelligent discussion of the papers by those in attendance, and, therefore, it has been decided to devote two days to the program this year, with a banquet Monday evening.

The tentative program schedules a meeting of the Board of Directors for Sunday evening, April 25. The business session will convene at 9 o'clock on the morning of April 26, with Harry E. Mock, president, in the chair, when reports will be received of the President, the Secretary-Treasurer, and of the Committees on (1) Teaching, (2) Publicity, (3) Legislation, and (4) on the Red Cross.

Special topics have been arranged as follows:

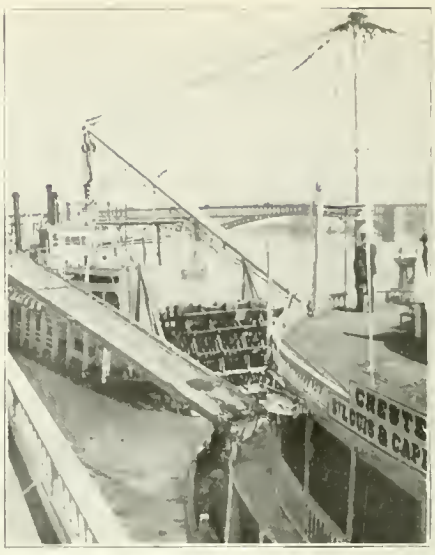
That the conception of industrial medicine has extended far beyond the early principles of emergency service is shown by tendency in conferences of industrial physicians to organize their work on a sound physiological basis. The evolution of physical standards for certain industrial requirements, the definition of conditions requisite for the maintenance of workers up to these standards, the psychic questions involved, and the hygienic and social problems concerned, are all reflected in the scope of the program announced for the conference at New Orleans. The topics include: "The Training of the Industrial Physician," "The Mentally Sub-Normal Wage Earner," "The Physically Sub-Normal Wage Earner," "Standardized Surgical Methods in Industry," "The Relationship of the Industrial Physician to the Venereal Disease Problem," and a symposium on "Industrial Physiology."

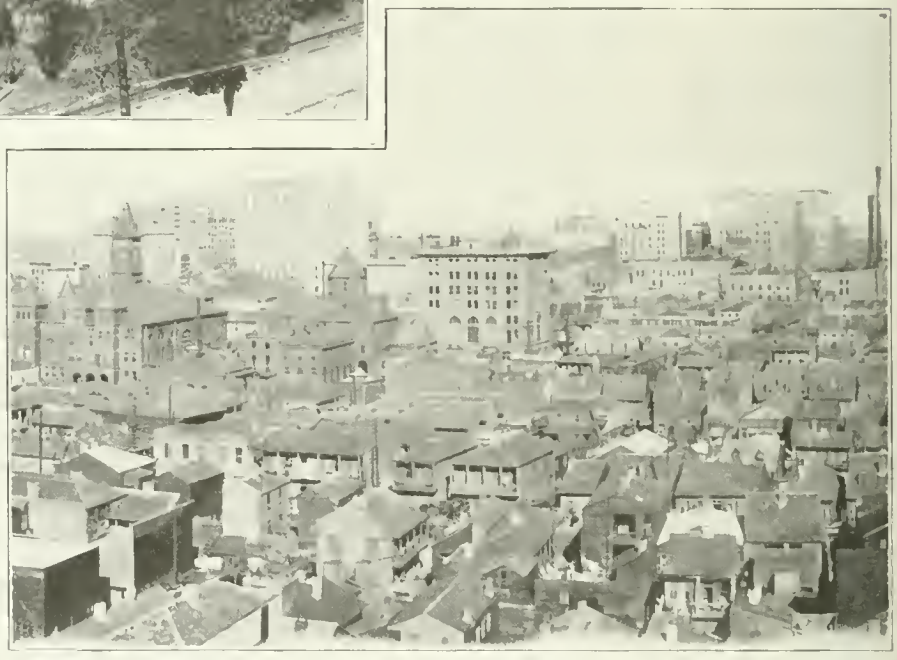
The program of Tuesday, April 27, will be devoted to at least four round tables dealing with such subjects as: (1) The problem of First Aid; (2) The Problem of Compensation for Sickness; (3) Higher Standards for Industrial Surgery; (4) General Discussion on the Report of the Committees on Teaching and Legislation.

The Association will endeavor at the conclusion of these round tables to take some definite stand in the subject of first aid in industry and go on record as to the limitations which should be placed on first aid procedures and upon those first aid workers who are not graduate physicians. The Association is also deeply interested in the problem of whether or not there should be compensation for those sicknesses and accidents not compensated for by the laws of the various states. It is probable that out of the general discussion at these round tables some definite stand will be taken upon this most important problem which now confronts the medical profession.

AMERICAN MEDICAL ASSOCIATION MEETS

IN NEW ORLEANS, April 26-30, 1920.





NEW ORLEANS is the happy choice of location for the early spring meeting of the American Medical Association, April 26 to 30, 1920. The old appellation, "The Crescent City" no longer describes the form of the city which has followed the bend of the Mississippi until it now describes a letter "S." Founded in 1718, the memory of its French Dominion is still retained in the titles of streets and avenues, and the contrast of the old French Quarters with the new district but emphasizes the charm of the old stucco walls, iron lattices, overhung balconies, urns and basins, half hid with vines. The moated and palisaded boundaries of early days are indicated by the wide, tree-planted and grassy avenues that lie along their course. Jackson Square is one of the quaintest and most picturesque of all the historic public squares in America. Under its old name of Place d'Armes it is associated with nearly every important event in the colonial history of Louisiana. The cathedral of St. Louis overlooks this square. Adjoining it on the one side is the Calaboza, dating from 1810, and on the other is the Cabildo, the government house and place of justice under Spanish rule.

New innovations, however, typify more than a change in architecture. Beauty in some spots may have given way to utility. Through municipal ownership of public utilities, New Orleans has made the most of her natural resources. Her wharves, warehouses, and elevators will be utilized by the Federal Steel Barge Line to revive traffic on big rivers. New boats and old will be operated from New Orleans with St. Louis as the northern terminal.

The location and configuration of New Orleans have made sanitation and drainage a difficult engineering problem that has been brilliantly met and has effected the transformation of the city from a malarious district to a healthful abode. The recent expenditure in plague prevention methods is but a part of a municipal policy. Their provision in health measures has won for this city an enviable record in the reduction of mortality rates from malaria and typhoid, the diseases which hereto constituted its greatest health menace.

Tulane University is notable among the higher institutions of learning in the United States. Its medical department, established in 1834, has turned out nearly five thousand graduates. Research work under the auspices of the Tulane School of Medicine has covered special problems in malaria, pellagra, beriberi, hook-worm, leprosy, and yellow fever. Training in public health work is provided by coordination with the Louisiana State Board of Health.

THE EXPERIENCE OF THE MEDICAL DEPARTMENT AT NITRO, W. VA.*

By DR. J. A. WATKINS, Medical Officer in Charge; Director, Industrial Medicine Division, Department of Industrial Medicine and Public Health, University of Cincinnati

THE war provided an unprecedented stimulus and opportunity in many branches of science and industry; none received a greater share of this stimulus than medicine; none was offered greater opportunity to demonstrate its true value as a national asset. The fact that a nation's strength depends basically on the physical and mental fitness of her citizens was brought to a state of clear and definite realization. It is a sign of the times that the progressive and sagacious in industry, and the various national governmental agencies took cognizance of this fact and delegated to the profession the responsibility of the acquisition and maintenance of health and physical efficiency of war workers. This responsibility was gladly accepted by the profession. Activities designed to better the health and increase the efficiency of war workers were not confined to members of the military personnel, but were prosecuted by and among civilians directly concerned with governmental war activities. An opportunity was thus afforded the profession of demonstrating modern medical methods of procedure in dealing with large groups of persons.

One of the many undertakings of this nature was the organization and conduct of the medical work during the construction and operation of the Government Powder Plant at Nitro, W. Va.

The construction of this powder plant and city was among the many undertakings incident to the unparalleled industrial expansion demanded of the Government to meet the exigencies of a war which had suddenly been thrust upon it. An irregular area of about eight square miles near Charleston, W. Va., was chosen by the War Department, and on this flat bottom farm land, through which the Kanawha River flowed, one of the greatest engineering feats ever attempted in the United States was successfully carried out. On January 1 the land was occupied by several small forms. It was fenced; corn stood in shocks; the farm houses and barns were occupied a typical West Virginia farming section. One hundred days later the Secretary of War, General Peyton March, and a group of distingushed men visited Nitro and found an industrial plant employing 22,000 people, manufacturing smokeless powder from the basic raw material. These visitors saw a small city of 1,2000 homes, schools, churches, a shopping district, a bank, and a theater. They inspected the second largest water purification plant in the United States; the largest acid plant; viewed fifty-five miles of interplant railway, and a mess room where 2,500 men sat and ate at one time. The party was accompanied by an escort chosen from among a mounted police force of 200 men. There was also a railroad station, an express office, a post office, and a motorized fire department. This party inspected a modern general hospital which could accommodate 600 sick and injured. But for lack of time they could have seen buildings erected from sunrise to sunset, a mile of standard railway laid before lunch, or a trainload of laborers discharged, inspected by medical officers, bathed and vaccinated, their clothes sterilized, the sick and the infectious segregated, and the well put to work within a similar length of time. Telegraph and telephone systems, complete and modern, were in constant operation. A car of material was unloaded each minute. Nitro plant and city seemed to grow by magic. The Secretary that day, in speaking to those working at Nitro, said: "It is the knowledge of such accom-

AN INDUSTRIAL CITY

In 180 days there grew, where farms had been, an industrial plant employing 22,000 people; a city of 1,200 homes, with schools, churches, theaters, and banks; a ninety million gallon capacity water purification plant; a telephone system; fifty miles of interplant railway; a six hundred bed hospital; and a motorized fire department.

Buildings were completed while the sun shone, and a car of material was unloaded each minute—all for the manufacture of powder for the western front.

The Medical Department was a distinct and important division and the Medical Officer in Charge was considered an executive of the plant and accorded courtesies in conferences and in matters of establishing policy and precedence in the work.

*The first of a series of three articles prepared by Dr. Watkins on the medical service at Nitro, W. Va., to appear in successive issues of Modern Medicine.

plishments as I have viewed today, as well as those of which we know in France, that has brought about a realization in Germany that we are a people who can not be conquered."

Conditions Without Precedent

As will be readily appreciated by the reader, the conditions under which the medical department operated at Nitro are not comparable to those previously experienced by the profession. The activities and results obtained must be considered with this in mind. Yet, notwithstanding the several adverse conditions under which the department operated, it is thought that the experience gained would be of interest to those members of the medical and allied professions who are interested in the development of industrial medicine; for it was from the viewpoint of an industrial physician that the work was attacked.

The site of Nitro as it appeared before the beginning of operations which almost like magic developed into a modern industrial city.

It will be gratifying to the medical profession, and particularly to those interested in public health and sanitary matters, to learn that in this instance the Medical Department was looked upon as a distinct and important division of the work at hand; that the Medical Officer in Charge was considered as an executive of the plant, and accorded courtesies in conferences and in matters of establishing policy and precedence in the work.

The view thus taken by the directors of this enterprise shows a marked increase of appreciation on the part of laymen as to the importance of public health matters. In the past, the recommendations of the medical officers were often not taken seriously, much to the detriment of the work at hand.

The construction and operation of an industrial plant and city such as Nitro create many problems of preventive medicine. Among these are the prevention of the introduction of communicable disease; the hygiene of housing; the acquisition of a safe supply of water and foodstuffs; a safe method for the disposal of sewage and wastes; and many general industrial hygienic problems, along with certain precautions to be taken in connection with the particular processes being carried on. The creation of a large residential area, in reality a small city, with stores, schools, theaters, imposes the same responsibility assumed by the health officer of an urban community. The United States Public Health Service assumed, in addition to the above duties, that of rendering medical relief in all branches and specialties and also an important service to the Federal Compensation Commission, as all employees of Nitro were beneficiaries of this Commission.

A brief mention of several factors bearing upon the general problems enumerated above may be of interest. First among these is the rapidity of increase in population. Second only to the rapidity of the grouping, was that of the grouping of persons representing widely divergent classes of society; previous environmental condition; intelligence; knowledge of modern ideas of medicine; habits of personal hygiene and cleanliness; state of health; age; race; and occupation. Early in February, when the Service first assumed responsibility, about fifty persons were employed at Nitro; 165 days later, about the date of the first industrial production, the population was in the neighborhood of 22,000. This does not fully indicate the sudden and great influx of people, for the labor turnover was at the rate of 620 per cent per annum. Those people were, in addition, grouped in a locality the prevalence of disease in which was such that importation of infection seemed at that time highly probable and did, in fact, later take place.

Other factors were as follows: The exigency of war necessitated extreme haste in construction and operation with the view to early and rapid production. Many basic hygienic laws were of necessity violated and dangerous risks taken. Foodstuffs, though in general procurable, were with difficulty obtained in Nitro. The water supply was rapidly becoming inadequate. Milk, even of reasonable safety, was not to be had. Improper attention of the medical profession of this locality in the immediate past.

The health organization of the state was unfortunately limited, both in available funds and activities. Preventable diseases were much too prevalent. A state of public mind desirous of better public health conditions was not evident in the immediate neighborhood of the plant. It was apparent, therefore, that with the influx of

There is little to suggest that in 180 days this scene was evolved from the typical West Virginia farming section shown on the opposite page. Its accomplishment was an engineering feat without precedent.

passable roads, continued rains, and rapidly increasing duty threw a burden on the sewage, garbage, and waste disposal facilities which was with difficulty carried. Under the same conditions the stabling of several thousand work animals on the plant, together with the oncoming of summer weather presented temporary difficulties. The workers at Nitro were not the hardiest nor the healthiest of men—because of the withdrawal by the operation of the Draft Law of those most free, as a class, of disease or ailment. In fact trainload after trainload of laborers arrived —ignorant, infested, alcoholic, drug addicted— combed by employment agencies from the lowest sections of our large cities.

Climatic Conditions

The West Virginia Geological Report states that in this section of West Virginia there are no long continued spells of excessive hot weather, while the cold spells are not exceptionally severe nor of long duration. The annual mean temperature is 56° F. The absolute minimum is 26° F. below zero, and the absolute maximum is 102° F. January and February (when construction actively first began) have an average mean temperature of 32.5° F. July and August (about when first industrial production began), have an average mean temperature of 76° F."

The prevalence of disease in the surrounding territory cannot be accurately given as the reporting of vital statistics had not received the thousands of persons from various parts of the Union, together with the unsatisfactory local status of health conditions, there would be presented the gravest possibilities for the introduction and spread of communicable disease.

On February 17 the personnel consisted of the Medical Officer in Charge, alone. On November 11, the list of personnel totaled about 800, of which number there were forty medical officers, eighty nurses, twelve skilled hospital employees— x-ray, laboratory and other technicians. Thirty were occupied in lay administrative and and clerical work, such as latrines, garbage and manure removal, water-carrying, and general sanitary policing. Between these two dates, of course, there were fluctuations, with a gradual tendency toward an increase to meet existing needs. All medical officers on duty were, with the exception of the author, acting assistant surgeons in the United States Public Health Service. The nursing staff was supplied by the Bureau of Nursing, American Red Cross. Only those nurses who by reason of age or marital state were not well suited for active duty at the front were thus detailed. This type of nurse can not do, as a rule, the amount of work which is ordinarily performed by members of the nursing staff of most hospitals. Many were past the active nursing stage of life.

The various trials through which employers throughout the United States were placed immediately after the enforcement of the Draft Law

were experienced by the Medical Officer in Charge. It was somewhat surprising, however, how easily the vacancies created in the rank and file by calling to the Colors of so many young and able-bodied men were filled by men and women who previously, by reason of age, physical condition, experience, or other causes, had not been considered as suitable for that particular class of work.

Statistics and Records

Extensive records were maintained, the most important of which were: Complete data as to physical condition of employees. Complete data as to physical condition of school children. Information regarding accidents and injuries. Vital statistics. Venereal control data. Hospital records.

A digest and study of these data would, no doubt, have been valuable, but unfortunately many records were lost in a fire.

Physical examination and medical supervision were provided for. Though it was not practicable under existing conditions to employ systematic or detailed intelligence or trade tests, each person before being placed on the payroll was subjected to a careful physical examination by medical officers. This department was conducted for the following purposes: (1) The prevention of introduction of communicable diseases; (2) the avoidance of employment of persons who either by reason of physical or mental disability might be a factor in the causation of accidents; (3) the discovery of remedial defects, in order that proper medical and surgical steps could be taken; (4) the determination of mental and physical status of the applicant for employment, in order that assignment to work could be made for which the applicant was best suited; (5) the exclusion of those who, either by reason of mental or physical disability, were incapable of performing labor of the type which was available; (6) the discovery of venereal infections and other infectious diseases in order that same could be hospitalized or treated, the labor supply thus being conserved, and the throwing out of infectious persons into society avoided; (7) the physical examination room, at the time of applying for work, afforded a most excellent opportunity for bringing the employee into close contact with the medical advisors. At this time various preventive measures could also be made known to the applicant; much popular hygiene and preventive medicine instilled and the confidence of the men obtained.

Periodical re-examination was made for the purpose of watching a certain physical or mental deficiency of an employee who was under observation, for change of occupation, or for the purpose of an early discovery of an occupational disease, intoxication, or injury.

The men shipped to Nitro, at Government expense, from various labor recruiting stations throughout the United States came with the understanding that they would be returned home at Government expense should they for any reason be refused employment at the plant. For this reason and also because it was desired to avoid the interstate transportation of disease, infected, or vermin infested persons, a system of medical inspection at the point of recruitment was also instituted.

After examination, applicants for employment were disposed of in one of the following ways: (1) permanently rejected; (2) temporarily rejected; (3) enrolled with disability noted; (4) certified for specified employment.

The scene of the varied industrial and social activities of a community of 22,000 people. Homes, schools, churches, a shopping district, a bank, a theater, a modern general hospital, and complete machinery for control are in full operation.

Several factors were involved in such classification of employees. The relative number of permanent rejections was small, both because it was the desire on the part of the construction agent to obtain every possible employee, and because

it was the desire to offer employment to every person capable of performing work. Only extreme cases were rejected. These fell into three classes: Class A—Those rejected at the request of the Federal Compensation Commission. Class B—Those rejected at direction of the Medical Officer in Charge. Class C—Those rejected at request of the construction manager.

Those rejected at the request of the Federal Compensation Commission were men who either by reason of mental or physical deficiency were liable to cause a serious accident, either to themselves or others, or both. Such men were the epileptics, those of deficient or impaired mentality, cases of advanced *tabes dorsalis*, the deaf and dumb mutes, and advanced drug addicts.

The men rejected on the initiative of the Medical Officer in Charge were those afflicted with a dangerous, loathsome, or contagious disease, which could not be readily cured or rendered noninfectious by reasons of the operating conditions at Nitro, with reasonable expenditure of time, money, and labor, and whose retention in the plant would be a source of danger to the public health. Among those so grouped were advanced tuberculous cases and the trachomatous, and the venereals who refused treatment.

The rejections at request of the construction agent were those who, because of a general physical disability, or the loss of a part, were not capable of performing any class of work available on this plant.

(To Be Continued.)

THE FUTURE OF MEDICAL PRACTICE

The *Ohio State Medical Journal* for March comments editorially upon an important investigation made by a special committee of the Cleveland Academy of Medicine on the subject of the organization and program of the Academy, and summarizes the report as follows:

"After enumerating accomplishments which have been made possible through strong organizations comprising men of similar interests in other lines of endeavor the report declares that only the great medical profession, as widely as it touches public life, has been blind to the desirability of such influential participation in community life and has failed to appreciate that the trend of the times in all other professions, businesses, and trades is toward a policy of assertiveness and aggressiveness in pushing the profession, if not the individual members of it, into the life of the community.

"The Future of Medical Practice" is the subject of the Committee's report, which declares at the outset and bears out through the remaining pages, that it concerns your own personal future."

"That the profession of medicine as now practised is in danger of being engulfed in 'state medicine,' and that unless the profession is properly forewarned and prepared, the doctor, whether general practitioner, surgeon, specialist or laboratory worker, may become a mere tool of capital, labor, and the politicians are also emphasized.

"The pauperization of the profession can be prevented by concerted and united action of its individual members" declares this Committee.

While the Committee's report undertakes to emphasize the profession's problems in Cleveland especially, it is absolutely pertinent to each physician in every community in Ohio.

As a summary, the Committee Report concludes with the following ten points:—

(1) The inefficient condition of the profession.

(2) The need for effective organization.

(3) The tendency of all classes in modern society to organize for attaining common purposes.

(4) The importance of the economic feature, if only for the maintenance of a scale of remuneration which will make good medical work possible.

(5) The need of an organization to secure: (a) Scientific programs; (b) economic justice, and (c) proper influence in legislation.

(6) It is desirable from an altruistic standpoint that organized medicine, *i. e.*, Doctors of Medicine, have due influence in public health education.

(7) A full time executive secretary is essential in a really efficient organization.

(8) To accomplish the purpose additional funds must be secured. This could be done by raising the dues.

(9) By the proposed division of membership into classes with a differential scale of dues no hardship would be inflicted on any member.

(10) Action must be taken promptly on account of pending legislation.

A more complete summary of the report is given in the same issue of the journal.

THE EPIDEMIOLOGY OF ACCIDENTS

In editorial comment on the "safety first" campaign being inaugurated in England by the National Safety Council of America, *The Lancet* of January 17 emphasizes the importance of careful preliminary study of the causation of accidents, not only in the risk of injury in a given case, but in the individuality of the person injured.

The study of the personal element in accident causation suggests that accident prevention, an important branch in the science of preventive surgery, is closely akin to preventive medicine. That accident is a chance occurrence is no more true than for an attack of typhoid, influenza, or tuberculosis. The accident rate of a given industry is not a chance one. "It is as regular from year to year as the occurrence of tuberculosis or cancer. . . . Not only is the total number of accidents thus regular, but the numbers due to special types of risk and affecting special parts of the body are similarly regular from year to year. Accidents appear to be dependent upon the personality of the persons injured and to represent reaction to environment. . . . Some persons have a tendency to sustain accident, just as in the field of medicine some persons have a predisposition to succumb to tuberculosis or some other infectious disease. . . .

"Just as education in personal health is today the best means for improving national health, so, in a 'safety first' campaign the aid of the individual and his education as to the existence of risk, with the way to avoid it, are the matters of primary importance to be considered. In matters neither of sickness nor of accidents can all element of risk be removed; but by improving health and alertness, rather than by fencing the public with protective guards, the influence of risk can be resisted."

TRAUMATIC SURGERY IN ITS RELATION TO WORKMAN'S COMPENSATION LAWS

By RAPHAEL LEWY, M.D., Chief Medical Examiner, State Industrial Commission, Bureau of Workmen's Compensation, New York City, Ex-Visiting Surgeon to Beth David Maternity Hospital, Chief O. D. P. Surgery, Beth Israel Hospital

HOW does surgery *per se* differ from traumatic surgery in its relation to workmen's compensation laws? To my mind, the latter implies emphasis upon the careful study of the etiology of trauma and upon temporary and permanent disability in their relationship to the ultimate permanent defects as they affect the earning capacity of the workman in his vocation.

MEDICAL SERVICE IN INDUSTRY

As to methods, per se, traumatic surgery varies but little from the accepted procedure in general practice. What makes for safety in the one case augurs well in the other.

The choice of method, however, is influenced by the occupation of the patient. A resulting defect that would be quite tolerable to a professional man might in the worker constitute a vocational handicap.

The best possible restoration, all things considered, in the Workmen's Compensation case calls for a keener prognosis and a more definite evaluation.

The conclusions presented in this article are based upon 28,313 examinations of men and women injured in their vocations and who, at the time of their physical examination, have exhibited either the remaining evidence of the injury or the defects consequent upon such injury.

Defects Resulting From Injury

At the New York State Industrial Commission, the patients are most frequently seen after they are discharged from surgical care, and at the time of their examination they present either the remaining evidences of injury or the defects which result from such injuries. The question may be asked, "Can you state from the remaining defects how the injury occurred, and what was the nature of the injury"? If we accept the axiom that upon any defect, whether involving the superficial or the underlying deeper tissues, bones, or viscera, nature leaves a distinct landmark, namely, a cicatrix, and if these cicatrices are studied carefully, one is very often enabled to state the causes and type of the injury. Differentiation must be made between the fine linear, non-pigmented, movable scar, indicative of a superficial wound which healed by first intention, and the scar which is adherent to the underlying tissues, and is evidence of slight inflammatory reaction; between the scar which is more adherent to the deeper tissues, and is evidence of an infection; and the non-movable, indurated scar, adherent to the important underlying structures, thus interfering with the mobility of the parts involved. This scar is evidence of serious infection of the underlying tendons. There remains to mention the deeper, indurated, adherent scar which is attached to the bones, and is evidence of infection and suppuration with destruction of underlying tissues.

Injury to the human body occurs in one of three ways: (1) The human body is the movable object and is projected against the stationary object. (2) The human body is the stationary object and a movable body impinges upon it or against it. (3) Man injures his body with the very tools, utensils, and mechanical appliances which he himself has created.

The Nature of Accidents

Accidents are frequently attributable to the posture which the workman must assume in his vocation. This posture differs greatly, of course, in the various occupations. It is instructive to contrast accidents which occur to men who work above ground with those occurring to men who work underground. The man who works above ground, and in particular the man who works at great heights—typified by the workers in the various building trades, more especially structural iron workers—is exposed to falls by reason of the insecure and narrow platform upon which he must stand. The injury either causes immediate death in consequence of the destruction of very important vital tissues or, if the injured man has sufficient resistance to overcome the immediate traumatic shock, there remain permanent, partial or complete, irreparable defects. Analysis of these cases shows that the individual receives either a fracture of the vault or base of the skull with its serious consequences, or a fracture of the upper part of the spinal column.

The semi-stooping posture of the man who works in excavations or in tunnels, while using pick and shovel, exposes the lower part of his spinal column to injury. Such a man is most frequently injured in consequence of heavy objects falling upon his back and is thus exposed to serious crushing injuries to the lower spinal column and pelvis, and to muscular strains of various sorts at or about the sacro-lumbar region.

There remains to discuss another class of working people—those who produce and who in the course of their occupations manipulate tools, instruments, and mechanical appliances, and who are exposed to the various injuries to the upper extremities, temporary or permanent disability resulting in consequence of mild or serious infections. The defects in this class of workmen are the cause of greater industrial loss than is produced in the workmen in other occupations. These conclusions are emphasized by the fact that out of the 28,313 cases we have examined, 4,083 were infections, for the most part involving the upper extremities.

Infections in Puncture Wounds

With regard to injuries and infections to the upper extremities, we may set it down as a *conditio sine quae non* of the more serious infections and their graver ultimate defects, the initial existence of a small punctured wound. Observation of my own large clinical material has failed to reveal a very serious general infection following an extensive lacerated wound, as in such wounds there is no retention and nature takes care of the drainage.

Let us describe first an ordinary injury daily seen in clinics, and which should be insignificant if adequate treatment is applied, namely, perionychia, or inflammation at or around the finger nail. This is an ordinary inflammation consequent upon some slight wound which, although sometimes painful, requires only the elevation of the cuticle from the nail, proper drainage, and a wet antiseptic dressing. It should heal without any functional defects of the parts involved if the surgery is adequate but not needlessly meddlesome.

The next infection is of greater importance, namely, panaritium or felon. This is an infection which occurs oftenest over the flexor surface of the distal phalanx of the finger, more especially of the index finger. It is generally in consequence of a wound punctured by some sharp instrument, usually a needle, and therefore occurs most frequently among tailors or needle-workers. As the wound is very minute the injured person may pay no attention to the injury at first, but within forty-eight hours, if an infection has set in, there is severe throbbing pain and enlargement of the tissues of the flexor surface of the distal phalanx. The slightest pressure over the infected part causes pain, and sometimes the pain is referable along the forearm up to the region of the axilla.

To understand this infection and its consequences more thoroughly, we must recall that the flexor tendon of the distal phalanx is attached to the base and does not go beyond that point. If it is remembered that phalanx wounds, which are the causes of infection, are oftenest near the tip and, therefore, do not involve the flexor tendons, it will be realized why this infection is most frequently a local infection of the tissues of the distal phalanx only. This infection requires adequate deep incision down to the phalanx, with proper drainage; it frequently remains localized at the primary site of infection and does not extend beyond it. The final result of these infections is always an involvement of part or the whole of the distal phalanx, suppuration taking place either through the original incision or, if after a certain time a sequestrum form, the pus escapes either through the original incision, if it has not entirely closed, or through a small bone sinus which persists as long as there is a loose sequestrum. In the latter case, the wound has to be reopened and the sequestrum removed. These infections are very painful at the beginning, and require a surgical disability up to eight weeks. There frequently result either temporary or permanent defects, there is a loss of part or all of the distal phalanx, or, in consequence of the suppuration, there is an adherent indurated scar with some involvement of the distal phalangeal joint.

The infection last described is and ought to remain a local infection, provided the surgical treatment is adequate, and the maximum defect ought to be, from the standpoint of compensation, equivalent to the loss of one-half of the index finger. The defect is more serious only when the infection occurs in old people. Our observations of these same infections in the aged have shown us that such patients develop marked fibrous changes at the interphalangeal and metacarpophalangeal joints, with serious functional defects. This complication is not an extension of the infection, but is due to the immobilization during the period of infection which evidently acts as a contributory cause of the secondary deformity. Another complication in the aged following this local infection, without any extension from the original seat of infection, is a limited mobility in the shoulder joint. The causes of this complication are not apparent.

Infection of Distal Phalanges

The infection of the distal phalanges is most often a local condition, very rarely involving the tendons, as these are attached to the base of the phalanges, a fact which explains why the infection resulting from a punctured wound beyond the distal phalanx becomes more serious as the extension of infection travels along the tendons to and beyond the palmar fascia, constituting a very serious complication. The cases of this last mentioned infection seen by the authors have resulted without exception in serious partial or total permanent deformities in which the functional defects involved part or all of the hand.

There is a very virulent infection which follows punctured wounds situated on the flexor surface of the thumb or little finger, most frequently at the proximal phalanges. To understand this serious infection it is advisable to recall the anatomical topography of the flexor tendons and synovial sacs in the forearm and hand. The flexor tendons of the hand are three in number, the *Flexor longus pollicis*, which is the flexor tendon of the thumb, the *Flexor sublimis digitorum*, and the *Flexor profundus digitorum*, which are the flexors of the other four fingers. These flexors are covered by a synovial sac which begins in the forearm above the annular ligament, goes beneath the annular ligament and is attached to about the middle of the four medicarpal bones where it terminates in a blind pouch, with the exception that it sends a fasciculus which covers the entire flexor tendon of the thumb as far as its attachment and also the entire flexor tendon of the little finger. It is due to this communication of the synovial sac with these tendons and to its close relationship to the annular ligament that a punctured wound involving the flexor tendon of the thumb and little finger causes such intense suffering and that the serious infections which extend along the hand and forearm are attended by serious ultimate functional defects.

The Occupations Most Affected

Our experience has taught us that this infection occurs oftenest among tin workers, butchers, and those who use pointed knives in opening fish or oysters. It occurs also among scrub women. The history and symptomatology are as follows: Within six or twelve hours after the alleged minute injury, which consists most frequently in a small punctured wound either over the flexor surface of the thumb or little finger, the patient suffers severe pain in the entire hand at and above the wrist joint. The site of the injury is very minute and at this time does not show evidence of an infection. Pressure over the site of the injury is not painful and even most careful examination reveals no evidence of local pus focus. The patient appears to be very ill, has a high temperature, and sometimes a chill. The most important physical sign of the infection is the semi-contraction of all the fingers and the inability to extend them. An attempt to force extension causes severe pain referable along the flexor tendons into the forearms. The general condition and this semi-contraction of the fingers causes the patient to try to secure relief. Failure to find a local pus focus makes it very difficult to institute the proper treatment.

It seems to be the consensus of opinion of surgeons that early operation is advisable. Such was also the opinion of the surgeons of the older schools here as well as abroad, but they were cognizant of the serious complication and serious deformities consequent upon the infection. They advised early, large incisions along the tendons of the *Flexor longus pollicis* or along the tendons of the *Flexor sublimis digitorum* of the little finger up to the annular ligament, and also incision into and drainage of the synovial sac to the side of the annular ligament. Some suggest that incisions go through the annular ligament exposing the flexor tendons of the forearm.

In my own employment of this treatment during clinical work for many years my results as to the relief of pain and ultimate functional mobility of the hand were very bad. In common with other surgeons, I found it necessary to reoperate on these cases until a pus focus could be located, which is most frequently situated beneath the palmer fascia or at about the thenar or hypothenar eminence. These very bad results which I have described I see even today in the course of examination of very large clinical material.

Treatment Before Surgery

As a result of careful attention to this subject during the last twenty years and from the observations of his later clinical work, it is our belief that this extensive functional deformity of the hand, wrist joint, and lower forearm can be prevented by converting the septic infiltrative focus into a local pus focus before operating The best procedure is the application of continuous heat over a moist dressing. The continuous heat causes an artificial hyperemia with a resulting increased local phagocytosis which causes the early breaking down of the infiltration, converting it into pus. Under such preliminary treatment for from four to six days preceding surgical interference, it is possible to locate the pus focus, and then with proper and adequate incision to lay it open and drain it. Drain-

age must be emphasized; not packing. Since adopting this mode of treatment our results have been better, that is, instead of a contraction of all the flexor tendons, which was formerly observed following the early extensive incision, we now find that this modified treatment jeopardizes only the one flexor tendon which is destroyed by the pus focus and, therefore, results only in a contraction of one or two fingers. Also, as adequate incision and drainage in a local pus focus are sufficient, secondary operation does not become necessary as was formerly the case.

To prove that this treatment is based on experience and has merit in its practical application one need only refer to the method of Professor Bier, which is also only a passive hyperaemia and has been vaunted in septic infiltration as accomplishing the same thing as the treatment above described.

As to the future treatment, this infection requires surgical care for months, and from a vocational point of view, the representative cases which we see in our examinations and which are treated by various surgeons in different institutions present the same irreparable defects which we observed years ago in our clinical work. From a vocational standpoint the deformities are usually equivalent to the loss of the entire hand.

Plastic Surgery for Deformity

As this concludes our consideration of the infections which involve the flexor tendons in consequence of minute injuries and as the cause of the various degrees of functional defects of the most important part of the body, the hand, we must refer to our experience of the so-called surgical *plastique* which is performed on these cases with the intention of restoring the function of the hand. When the defect in mobility results from an indurated scar adherent to the underlying tissues, the results after competent surgical interference are fairly good; but, when the immobility results from the destruction of the tendons themselves, surgical interference, although producing a better cosmetic effect, has in the cases that I have examined not been very beneficial from the standpoint of functional mobility of the hand. The bad results are very often accounted for when the defect of mobility is not only in the tendons, but when there are also changes in the phalangeal joints which cannot be overcome by surgical procedure.

Infections involving the extensor surface of the hand and forearm are most often of vocational origin and are produced by irritating substances, sometimes chemical, sometimes metallic, causing the so-called furunculosis or pustulovesicular infection. They occur among people working in furs and dyes, are not easily amenable to treatment, recur often, and need not only local treatment, but require autogenous vaccine treatment as well. We have lately had opportunity of studying these cases among munition workers, in whom this pustulovesicular infection occurs in consequence of irritation by small metallic particles which are saturated with an oily substance. The infection is painful and in some cases may cause secondary metastases and prove fatal. We have also seen a few cases of anthrax among workingmen who come in contact with hides. The infection preceded by an injury was most frequently on the side of the face, near the angle of the lower jaw. We have observed that early excision of the pustule and vaccine treatment benefit most of these cases. We have also seen two cases of actinomycosis of the face resulting from the workman's contact with hides. The infection was preceded by a local trauma of the skin. The infection in both cases was over the tissues of the malar bone.

Remarks on General Infections

Local infections of the tissues of the extremities which are followed by pus foci, with or without a lymphangitis or a lymphadenitis are very seldom complicated by general systemic infections, although they are serious from a surgical point of view and requiring a long surgical disability with certain functional defects of the part involved. It is the minute local infections, without formation of pus foci, ushered in by a chill and high temperature which constitute the serious systemic infections that jeopardize the life of the patient.

Remarks on Hematogenous Infections

By hematogenous infections we understand those which enter the general system through the circulation. They either manifest themselves immediately during the acute infection or may remain dormant for many months or years until a nidus is created.

A suppurative infection of any part of the body may have healed entirely from a surgical point of view, and the individual may not show evidence either by physical signs or subjective symptoms that he suffered from a general infection as a sequel of his original infection. Such an interim may be a long one, until the same person meets with a secondary accident to a part of the body distant from the original infection. This secondary injury causes a *locus minoris resistentiae* and is nidus for the development of the bacteria which were entirely inactive up to the time for this secondary injury.

The author can cite many such examples long

since seen in clinical experience and again lately in the examinations made for the Workmen's Compensation Commission. It is possible to activate not only a previously dormant hematogenous septic infection by an injury, but also a dormant tuberculosis or a syphilitic infection. This is of considerable importance as they are often points of divergence in discussions and disputes between physicians representing the injured man and the insurance carriers. The question is often brought up whether certain serious infections are attributable to a secondary injury or to a prior infection. Whether the injured person has had syphilis or a latent tuberculosis, or a hematogenous infection in consequence of a previous infection, if, as a result of an injury, his dormant general infection is activated, and in consequence thereof he is disabled, it is the author's belief that he is entitled to compensation for his disability and, if such an infection results in death, the death is compensable.

The most virulent of destructive infections fortunately, however, of infrequent occurrence, is the infection caused by the *Bacillus aërogenes capsulatus*. Without going into a detailed description it suffices to say that this infection most frequently results from a minute punctured wound, oftenest in the lower extremity, at the plantar surface of the foot, in consequence of stepping on a rusty nail. The site next in frequency is an infection of the upper extremity from a wound at or about the wrist joint. Those who have sufficient resisting power to overcome the infection are left with permanent defects, but most of the cases are fatal.

Duration of Disability

The length of the period of disability is relatively of greater import in the compensation case, as difficulty may arise in determining the degree of disability represented by a stiffened joint or the limited use of a member. A word about the duration of disability from these infections from a surgical and vocational point of view in their relationship to workmen's compensation laws might be appropriate. In ordinary uncomplicated perionychia the usual surgical disability is up to about four weeks, and there is no permanent vocational disability. In panaritium or felon, involving only the distal phalanx, the surgical disability may last as long as ten weeks and the vocational defects may be equivalent to the loss of half a finger. In the other serious infections of the hand, beginning either in the thumb or little finger, there may be a surgical disability for as long as six months, and a vocational disability equivalent to the loss of the greater part of the hand.

NATIONAL PHYSICAL EDUCATION SERVICE

Representative Simeon D. Fess of Ohio, who is chairman of the Committee on Education in the House, has introduced a bill initiating physical education on a national scale. Senator Arthur Capper of Kansas has introduced a similar measure in the Senate. The fundamental aim of the bill is to give every child between the ages of six and eighteen years the opportunity for a periodic health examination, practical instruction in the principles of healthful living, and training in physical activities which insure a high degree of resistance to disease and a properly coördinated, physically efficient body.

The schools, with the cooperation of the departments of public health, furnish the most effective existing machinery through which to work out this program. The sponsors of the bill have kept in mind the dual aim of safeguarding state autonomy and insuring that the work done will measure up to reasonable minimum standards. No arbitrary authority is given to any Federal official or department. Federal authority is to administer only the explicit provisions of the Act.

MEDICAL COLLEGE ASSOCIATION ELECTS OFFICERS

At the annual meeting of the Association of American Medical Colleges held in Chicago, March 2 and 3, Dr. William Pepper, Philadelphia, was elected president; Dr. Thomas Hough, Charlottesville, Va., vice-president; and Dr. Fred C. Zapffe, Chicago, was re-elected secretary-treasurer. The new executive council consists of Drs. Irving S. Cutter, Omaha; Isadore Dyer, New Orleans; James Ewing, New York City; Charles S. Bardeen, Madison, Wis.; and George Blumer, New Haven, Conn.

NATIONAL TUBERCULOSIS ASSOCIATION MEETS

The annual meeting of the National Tuberculosis Association will convene in St. Louis, Mo., April 22-24, 1920. It is said, since the war, that the question of tuberculosis eradication was never more urgent than now, nor has it ever been more appreciated that a tuberculosis campaign is a general health campaign.

This conference just precedes the American Medical Association meeting in New Orleans and health workers en route to New Orleans should include the Tuberculosis Association convention in their itinerary.

The following chairmen are in charge of the various sections of the annual meeting of the National Tuberculosis Association, to be held in St. Louis, Mo., on April 22, 23 and 24.

Clinical Section—Dr. George E. Dock, Professor of Medicine, Washington University, St. Louis.

Pathological Section—Dr. Eugene Opie, Professor of Pathology, Washington University, St. Louis.

Advisory Council—Dr. Allen W. Freeman, Secretary, State Board of Health of Ohio.

Sociological Section—Dr. H. W. Hill, Executive Secretary, Minnesota Public Health Association, and President of the National Congress of Tuberculosis Secretaries.

Nursing Section—Miss Edna L. Foley, Superintendent, Chicago Visiting Nurse Association. Miss Foley has been on leave of absence for the past six months, doing tuberculosis work under the Red Cross in Italy.

Headquarters will be at the Hotel Statler.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

DEATHS DUE TO ACCIDENT A PUBLIC HEALTH PROBLEM

DEATHS due to accident or "external causes," as they are nominated in the census reports, have generally been treated as if they lay beyond the sphere of the activity of the health officials. With an increasing realization of the fact that the objective of the modern public health campaign is the prevention of preventable disease and disability and death in every form, it seems clear that the accident hazard deserves the serious consideration of the health officer.

The 1918 mortality statistics for the Registration Area which have just been issued show external causes ranking fifth as a cause of death, following influenza, pneumonia, organic diseases of the heart and tuberculosis; and in ordinary years they stand fourth. The death rate from "external causes" in 1918 was 100.6 per 100,000, equivalent to 5.6 per cent of the death rate from all causes, an element in the total mortality large enough to constitute a major problem for the sanitarian. The largest single factors in this group of causes are accidental falls—12.6 per 100,000; suicide—12.1 per 100,000; railroad accidents and injuries—10.5 per 100,000; automobile accidents and injuries—9.2 per 100,000; and burns, excluding those due to conflagrations—8.1 per 100,000.

It is encouraging to note that the safety movement is making headway and that the death rate from "external causes" is gradually declining. The rate of 100.6 for this group of causes of death recorded for 1918 compares favorably with corresponding rates of 108.8 for 1917 and of 107.9 for the period 1906-10; yet accidental falls killed more people than typhoid fever in 1918 and railroad accidents almost as many as measles.

The methods which promise success in the reduction of accidents are clearly indicated by the successful campaigns which have been waged by many industrial concerns against hazards of this type. The first essential is included under the general heading of Safety Engineering, the construction and management of the places where men work and live and move about so that every avoidable opportunity for accidental injury may be minimized. The other essential is the conception of "Safety First,"—the cultivation of a sense of personal responsibility. No amount of prevision on the part of public authorities or employers of labor can protect the man who "takes a chance."

In particular, there is one "external cause" of death which is not decreasing but increasing, year by year,—death from automobile accidents and injuries. While other types of accident hazard have more or less steadily diminished, the death rate from automobile accidents has increased from 1.8 in 1910 to the figure of 9.2 recorded for 1918. This is, of course, no evidence of increasing carelessness but merely of increasing use of motor transit; yet the obligation is none the less clear to meet the growing problem by the vigorous enforcement of sound traffic regulations.

To quote from *Delaware Health News* for January: "In considering this large number of deaths from accidental causes it must be borne in mind that these deaths are for the most part of strong, vigorous persons, many of them healthy children; and the loss to the state is much greater than the loss of an equal number of persons who are suffering from some chronic disease for which there is no cure. A campaign of education regarding accident prevention should therefore be given the same serious consideration as a campaign of education regarding disease prevention and, if this high toll from accidents cannot be materially lowered by education, then those responsible for these deaths must be dealt with so severely that their example will serve as a warning to others that the life of no person can be placed in jeopardy with impunity."

EDITOR.

A CRITICAL SURVEY OF PUBLIC HEALTH TOPICS

By JULES SCHEVITZ, General Secretary, Oklahoma Tuberculosis Association, Oklahoma City, Okla.

I. Food Restriction and Mortality.
II. The Biology of Public Health Problems.

I. FOOD RESTRICTION AND MORTALITY

AN interesting account of the effect of food restriction during the war on mortality in Copenhagen is contributed by Hindhede[1], Danish nutrition worker. The allied blockade had considerably reduced the supply of bread cereals in Denmark, which had previously been imported, so that the principal foods used were bran bread, barley porridge, potatoes, greens, milk, and some butter. Pork production was very low and beef was so costly that only the rich could afford to buy it. It is evident, therefore, that most of the population was living on a milk and vegetable diet.

This low protein experiment with about 3,000,000 subjects began in March, 1917, and was in full force by October, 1917. During the year ending in October, 1918, the death rates for epidemic diseases and tuberculosis fell to 66 per 10,000, representing a decrease of 34 per cent as compared with the average rate for the previous seventeen years.

In the words of the author, "The death rate for Denmark for the year October, 1917, to October, 1918, was 10.4 per thousand. It never had been lower than 12.5, the figure for 1913-1914. A difference in the death rate of 2.1 per thousand for a population of 3,000,000 means a saving of 6,300 lives. Hence, the saving of lives in Denmark as a result of the Allied blockade was considerable."

Whether the national use of a low protein diet was itself responsible for this decrease in the general mortality is open to question. It is to be remembered that during the year under consideration the output of alcoholic beverages was greatly reduced, and this fact undoubtedly operated in favor of a decreased mortality.

There seems to be a prevailing opinion among nutrition investigators that the average diet contains too much protein. The use of vegetables and bran is believed to result in better physical condition.

Lactovegetarianism is considered by McCollum[2] as the most highly satisfactory plan which can be adopted in the nutrition of man. This diet consists of the combination of vegetable foodstuffs taken along with a sufficient amount of milk to make good their deficienies. As Hindhede observes, an unusual amount of bran was consumed by the people of Denmark during the period of food restriction. Added to this was the milk and some butter which aided in making the diet in many respects ideal.

II. THE BIOLOGY OF PUBLIC HEALTH PROBLEMS

THAT the biologist should have an important place in formulating and executing our public health program because of his broad scientific preparation is the plea of Prof. Raymond Pearl, of Johns Hopkins University, in a discussion on "The Significance of Some General Biologic Principles in Public Health Problems."

Professor Pearl questions the achievements of our present public health program and suggests that the failure to control tuberculosis and other diseases has been due largely to our neglect in not recognizing the significance of certain fundamental biologic principles in the causation of disease. Among the desirable results from the wonderful development of bacteriology there was also the unfortunate one of swinging the pendulum of medical thought far off the sound general biologic pathway. Too little emphasis has been placed on the constitutional factors and too much on the environmental causes. Frank recognition and intensive investigation of the fundamental biologic factors in the problems of public health are essential to further real progress toward their solution.

As an example of the value of biologic interpretation of health phenomena, the author recounts the result of his studies into the variations of the explosiveness of the 1918 influenza epidemic. Careful statistical analysis shows that the ordinary demographic and environmental influences did not account for the differences in the explosiveness in the various cities studied. The restrictive and repressive measures used during the epidemic on the different cities had no bearing on the course of severity of mortality. It was found, however, there was a very high correlation between the explosiveness of the out-

3. Pearl, Raymond, Ph.D.: The Significance of Some General Biologic Principles in Public Health Problems, Jour. Am. Med. Assn., 1920, lxxiv, 275

break of epidemic mortality and the normal death rate from all causes in the same community. On further analysis the correlation existed to an even higher degree for three great causes of death; namely tuberculosis, organic heart disease, and acute nephritis, and Bright's disease, which are primarily dependent on the functional breakdown of the lungs, the heart, and the kidney.

Investigations by Pearson and by the author indicate that the incidence of pulmonary tuberculosis determined to a very large degree by constitutional or hereditary factors rather than by environmental factors. Cardiac and renal diseases are recognized as primarily organic, so that the "biometric analysis demonstrates that populations particularly subject to these constitutional diseases were the populations which were least able to withstand the onslaught of an especially virulent epidemic."

If it be true that heredity imposes a hard and fast limitation on the effectiveness of palliative or control measures for public health, then we must recognize the need of serious revision in our present public health methods.

CINCINNATI SURVEY OF THE AFTER EFFECTS OF INFLUENZA

By PAUL MASON, Cincinnati, O.

What does experience profit a man if he does not analyze its elements and bring its lessons forward so as to eliminate in his work of today the mistakes of yesterday?

Out of the most violent ravages of epidemic disease, intelligent survey can evolve added skill in meeting a like situation and may broaden the compass of medical activities.

An exact conception of the damage done is the first step in remedial measures which must include a régime adapted to the permanently handicapped, an economic prop during temporary disability, and correction as far as possible of depressing after effects.

THE Cincinnati, O., Chapter of the American Red Cross and the health department of the city, working with the financial support of the American Red Cross Society and receiving the cooperation of a number of life insurance interests, among which the Metropolitan Life Insurance Company of New York has been particularly active and helpful, has just finished and reported on the first complete survey in the country of the after-effects of influenza covering a definite territory and population. The survey is impotrant, and the report is of incalculable value, not alone because it is the first of its kind, but chiefly because of the systematic way in which the survey was organized,—the high character and professional standing of the physicians, surgeons, and nurses who conducted it, and the fact that it covered a metropolitan area, including Cincinnati and Hamilton County, with a population of more than 600,000 that had been hard hit by the disease.

Study Effects, Not Causes

Little effort was expended to determine the cause of the disease, although nothing was ignored that might throw light on that subject, but no definite results were achieved as to its etiology. The importance of the survey lay not so much in fixing causes as in defining, delimiting, and removing or counteracting the effects of the disease, and all energies were directed to this end. Dr. Lee K. Frankel of the Metropolitan Life Insurance Company, who examined closely into the system followed and the results as they were developing when he was in Cincinnati attending the convention of the American Public Health Association as president of the Association, gave it his heartiest endorsement, and subsequently wrote that "Cincinnati is doing the first real work in this respect of any city in the country."

Partly as the result of his interest, and partly as the logical sequence of the splendid work for health conservation that is being done by his company, the Metropolitan field force in the territory contributed largely to the success of the methods and the far reaching results attained.

The results of the epidemic, as revealed by the report on the survey, were nothing less than appalling with respect to the general health of those attacked by influenza, this class constituting a very large proportion of the population, and in its consequent influence on mortality, unless the sequelae are counteracted. The report shows also the possibility of this counteraction or removal, and in that respect mitigates the gloomy outlook revealed by the statistics of after-effects.

Outstanding features of the report are the high proportion of cardiac cases, covering a wide range of seriousness; the abnormal development of tuberculosis and pre-tubercular conditions, and the large number of throat affections. Hardly less striking is the absence of affections of the urinary organs from the statistical record. These apparently were so infrequent as to be regarded as of little importance, and, therefore, are included in the general classification of "Other conditions."

The scope of the survey and the wide range of ailments found are set forth in the following figures:

Total number registered	13,772
Total number examined	7,058
Number under 3 years of age	665
Number from 3 to 10 years	1,117
Number from 10 to 20 years	1,116
Number from 20 to 40 years	2,749
Number from 40 to 60 years	1,179
Number over 60 years	232
Total number examined	7,058

Racial and sex distribution was as follows:

	Male	Female	
White	2,608	4,246	
Black	83	121	
Total	2,691	4,367	
Grand total			7,058

Of this number 5,624 required medical attention and 1,434 were examined but not recommended for treatment, and 2,015 were re-examined.

Defects and Diseases Diagnosed

This classification includes all of those requiring medical attention, a few of those not recommended for treatment, and a considerable number of patients who had two or more ailments.

Communicable disease	1
Defective vision	507
Diseases of the eye	184
Defective hearing	166
Diseases of the ear	134
Hypertrophy of tonsils and adenoids	816
Diseases of respiratory tract	913
Defective nasal breathing	591
Pulmonary tuberculosis	183
Pre-tuberculosis conditions	265
Asthenias	828
Cardiac diseases	643
Defective teeth	1,208
Skin diseases	97
Venereal diseases	45
Other conditions	2,352
Total	8,933

During the four months of operation, from May 1 to September 12, 1919, 13,772 influenza subjects were listed at the thirteen stations; 7,058 were examined; and 5,624, or nearly 80 per cent, were found to be in need of some kind of medical, surgical, or dental interference. Those re-examined from time to time—observation cases—numbered 2,015.

The number of cardiac cases (643) found, is decidedly high, and embraces the usual run of lesions from ordinary irregularities down through the functional and organic lesions. Careful examination of statistics bearing on the high death rate following preceding influenzal epidemic reveals the fact that a large number of deaths were due to cardiac diseases.

Illustrating this point, it is noted that following the epidemic last spring, an unusually large number of prominent citizens died suddenly, and inquiry invariably elicited the history of an attack of influenza during the pandemic. Such issues being usually cardiac in origin, this is supposedly the cause in most cases; but there is no means of determining what type of heart disease was responsible, whether a myocardial affection, a conduction defect, or a serious valvular lesion. In this connection the question arises, could such a condition be diagnosed in a routine way; and, if so, could an adjustment of corporeal activity or other directions prevent the fatal outcome?

These and other considerations prompted Dr. Julian E. Benjamin to make special cardiac examinations on selected cases found complaining of cardiac distress. Complete electrocardiographic and polygraphic observations will be made the subject of a special report, but the preliminary report is filled with interesting and valuable data.

The greatest distress was noted among those who had influenza during the first wave in October. Symptoms complained of in most cases were inordinate fatigue or exhaustion, weakness, dyspnea on slightly more than normal exertion, tachycardia, and precordial distress.

Cardiac examinations presented two definite points of diagnostic interest in many cases: (1) Cardiac rate above normal which did not return to the quiet rate three minutes after exercise. (2) Diminution in intensity of the first mitral sound, making it very difficult to distinguish the first from the second sound. Most of the cases showed no organic heart disease. The few organic lesions that were detected had existed for several years, but undoubtedly were aggravated by influenzal infection.

The number of tuberculosis cases is striking in the respect that they are in nearly every instance new cases, never before reported to the health department. Of the 183 reported cases, 61 were confirmed either by x-ray or sputum examination, and the remaining 122 cases presented sufficient clinical evidence to warrant a tentative diagnosis of "incipient pulmonary tuberculosis."

The follow-up work on tuberculosis cases is described as having been particularly well done, and as approaching, as nearly as possible, 100 per cent efficiency.

Among the 263 pre-tuberculous cases the report includes those with a little roughened breathing, flat chests, enlarged glands, positive von Pirquet, but no pronounced auscultatory symptoms. It was found by experience in the clinics and confirmed by many practitioners that nearly 50 per cent of the children under five who had had influenza gave a positive von Pirquet.

The asthenic group, so called on account of the symptoms presented, furnished a very interesting study, and one of considerable value. The largest immediate results, so far as treatment was concerned, were seen in this class. For the most part under-nourished, with anemia of more or less severe grades, lacking in physical strength and initiative, yet without any demonstrable pathology,—these cases enjoyed a speedy return to normal with rest and a course of stimulating tonics.

Nose and throat cases were quite numerous during the course of the work, and the nose and throat specialists performed 190 tonsillectomies and adenectomies.

The x-ray was used in the examination of 184 patients, and 449 plates were made as aids to diagnosis or in confirmation thereof.

Other defects and diseases in the main were not chargeable to influenza, although nearly all were aggravated by it to greater or less extent. Even defective vision, in a few instances, was remotely influenced by the influenzal attacks.

Defective teeth are touched on in the report only in their effect on the general health, in cases in which their detrimental influence tended to make the inroad of influenza easier rather than being affected by it.

Remedial Measures Employed

The survey was accompanied by a definite and effective system of relief for those who needed it, extending in many cases to material financial assistance. Shattered homes, health, and income, —inability to work,—impaired efficiency, and loss of earning power, mental anxiety and distress, coupled with the high cost of living, completed the chain of horrors following the ravages of the epidemic.

Its economic effects first were felt by the various social agencies early in February. Every organization and agency caring for dependents had more applicants than it could care for. The Cincinnati General Hospital had cared for 151 families consisting of 553 persons, every member of which had been stricken. More than 50 per cent of the wage earners in 400 dependent families cared for by one organization had been unable to return to work.

Therefore, the plan was adopted of carrying forward, side by side, the work of relief and the task of discovering and removing or counteracting as far as possible the after-effects. The American Red Cross financed the movement with a total of $50,000—$25,000 for each branch of the work. The form and manner of relief has been as effective as the clinical researches, and the local chapter of the Red Cross, which had direction of the activities, has completed its task with a balance of $7,058 remaining in the medical fund, a considerable part of which probably will be transferred to the permanent relief fund as the relief section is expending approximately $1,000 a week in the care of 150 families.

Every Metropolitan agent and solicitor in Hamilton County took an active part in the work, and the health section of the Metropolitan Life Insurance Company gave invaluable assistance to the health department of the city, which had direct charge of the clinics. The thirteen health stations have been closed but have been superseded by night clinics at various schools, conducted by the same men and women, and in the same manner,—so that while the original program has been completed, the work is going forward without interruption, and with results that compare favorably with that already reported on.

APPOINTED DIRECTOR GENERAL

Ward Bonsall, associate director of the Red Cross Department of Civilian Relief, has been appointed Director General of the Department, succeeding J. Byron Deacon, who recently resigned. Mr. Bonsall came to the Red Cross on April 1, 1919, as Director of Information Service in the Department of Civilian Relief. On December 8, 1919, he was appointed Associate Director General.

L. E. Stein, who has been serving as Associate Director of the Bureau of Information, has been appointed Assistant Director General of Civilian Relief.

THE NEED OF MORE LABORATORIES

That clinical laboratories in a community do not take the place of public health laboratories designed and operated to handle work with public health significance, is the opinion of Dr. Martin Dupray, chief of the Division of Laboratories, Illinois State Department of Health, in the March issue of the *Illinois Medical Journal.*

The public health laboratory operates with the object of disease prevention and epidemic control. It is the proper sphere of research work requiring large numbers of specimens for comparison.

In most communities in Illinois there is urgent need to develop both clinical laboratories as aids in treating the specific case and public health laboratories to supplement health measures. The distant laboratory, no matter how well conducted, cannot be as useful as a local laboratory.

PUBLIC HEALTH NOTES FROM THE VOSGES*

By THEODORE C. MERRILL, M.D., Conferencier, Foyers du Soldat; Acting Assistant Surgeon, United States Public Health Service

THE enormous mass of medical material, —method, innovation, and record,—will, when assimilated, shed an inundation of light on the world and also open numerous problems for solution by enthusiastic students for many years to come. The value of the information collected by the Army and Navy, the Red Cross, the Rockefeller Foundation, and other active organizations is inestimable. Some time will naturally elapse before this huge amount of material can be presented, but the sooner it can be offered to the world the better, for the sake of every public, every nation, and every interest now intent on the task of extrication from the embarrassments caused by the war.

HEALTH THEORY AND PRACTICE

When nations compete with one another in racial betterment, and health becomes a matter of national pride, then will there come a better era in the world.

The great impetus to health work from the war has come from the comparison of conditions and the need that has been brought home to every nation of conserving the life and strength of its members.

The difficulty of achieving effective health work anywhere is to get health theory and health practice on a somewhat similar basis. The universal observance of a comparatively few rules would, in a short time, transform present health conditions.

"Show" Features in Health Work

In flights up and down the eastern half of the west front, flights made for the purpose of interesting the French in American methods as applied to public health questions, it was impossible to avoid making a few notes, although provided neither with time nor opportunity to do any genuine survey work. Addresses, or conferences, as the French call them, given under the auspices of the Foyers du Soldat, which was my service, had to be fairly entertaining as well as instructive. It was practically infeasible to attempt these conferences without the "show" feature—and, for that matter, the show is perhaps the very best method for imparting information vividly and unforgettably, provided the show be really excellent. Show material in this case consisted almost solely of lantern slides and moving picture films, cinema films, so-called. It is very difficult to get effective and dependable material of this kind. At the outset I wish to acknowledge most cordially the courtesy and assistance of the Red Cross and Rockefeller Tuberculosis Commission, as well as the kindness of the French Ligue contre l'Alcoolisme. Without the cinema films and lantern slides which were lent to me by these organizations, the attempts at public health instruction made by the Foyers du Soldat would have been severely handicapped. A film devoted to tuberculosis and treating the subject in a humorous fashion was very popular with the French, as also was a dental film created by the New York Dental Association. The Foyer also used a so-called hygiene film called "The End of the Road," and various posters and other printed matter were widely distributed. It was my good fortune to lnd a commercial film showing the method of physical examination and record in use by the Life Extension Institute of New York, and films showing athletics and gymnastics were utilized whenever possible.

Owing so largely to the help thus rendered, one may fairly feel that the Foyer conference labor was not expended in vain. It may be remarked also that the conferences extended not only to the French but to many colonial troops, Sengalese, Algerians, Haytians, Annamese, and others, and to hundreds of Russians and Poles. They were given nearly always in French, German being used occasionally for Russian troops who did not understand French. For many Russians the address was made in French and translated to the men by some Russian

Typical village street, the children's playground. They seem to think no automobile could hit them.

officer who understood French. Being thus given under American representation, this conference work is very happy in being counted among influences which had the possibility of putting America in the best light as an unselfish servant of suffering humanity. I speak with conviction when I say that every man placed by America in a foreign land has within his grasp a marvelous opportunity to glorify or degrade his country and either to strengthen or to weaken her influence with other nations. Practically without exception, the public health agencies and their personnel overseas acted and continue to act in such a fashion as to make America beloved as the star among struggling peoples; not that America's stellar rôle is orbitally perfect, either.

Closet bed (lit clos) of Brittany. It is kept beautifully clean, but the Pullman berth has it bested for ventilation. The cradle, however, is human.

Making up the closet bed, pretty but stuffy. In Anvergne beds much like these are built into the wall.

Prominent Health Problems of France

Tuberculosis and alcoholism admittedly constitute the foremost public health problems of France. With these run closely questions of the birth rate, infant mortality and venereal disease. France's active thinkers accept the facts and propose remedial measures. I do not find anywhere in France a tendency to blink the issues involved but on the contrary I find a very serious consideration of such issues, perhaps almost pessimistic in tone. Certainly the spirit is not that of the "fool optimist."

With a tuberculosis rate not only much higher than ours or that of Great Britain, but a rate that has remained almost stationary for ten years, it is no wonder that French attention is aroused. Actively associated with this question are alcoholism and sanitation. In some regions of France there is extensive use of highly alcoholized beverages, such as cognac, calvados, and mirabel,—calvados a Norman cider-drink of the hardest variety, mirabel, a Vosgian brew of plum. In such regions drunkenness is common and much in contrast to the condition obtaining where drinking is limited to light wines and beer. The cognac, calvados, and heavy liquors must go, and the French know it.

Sanitation? There is no more interesting subject in France than that. Theoretically and sporadically the French sanitation is the best in the world. As a national practice it is admittedly lacking.

Simple method of municipal drainage. Frequently flushed, a street may not be so bad, but flushing is often lacking.

The sanitary engineering of Paris is admirable, notwithstanding the superficially alarming quality of the frank public urinal, whose danger, in Paris at least, is far more apparent than real and which is not without advantages, even in the eyes of many Americans. The rural places, however—ah, that is another tale. If only immediate convenience in the disposition of body discharges is to be consulted, then, to protect the public, such disposition must be rendered safe, and that is not done in the little towns and villages. Not all American small towns need preen themselves particularly, for I seem to remember such not one step in advance of the crudest, most careless exemplars of casual public health in France.

The daily bath in France was a ceremony before the war and practically ruled out by war and post-war conditions. In one town which I recall, the French officer had installed a simple douche for his men, just like the douches in ordinary use at our soldiers' barracks. However, that was

not usual. Bathing in France is done less frequently than in America, but perhaps the people are going to do better, especially if they can be provided with soap, which has been so expensive and hard to get. Also, warmth in the home is necessary for proper bathing, and here again looms the war, with the serious fuel deprivation caused by it.

Parenthetically it may be said that, in using the terms "France" and "the French," one is likely to permit these expressions to represent a wholesale and national, instead of a local and parochial, idea. America knows almost not at all the life of the shut-in community, the community that lives by immemorial custom, the community that creates the folksong as well as the wall bed, or *lit clos*. We still have a few Kentucky mountaineers, a few Arkansas travelers who do not travel, but as a general rule we circulate. We don't cling to a hampering, if romantic, past. And so let us remember that France is a congeries of communities, self-living and self-dying, and that it is quite difficult to say that this, that, or the other is typically "French." The war will probably result in effecting a change in this respect, as the pressure of the crying public health problems may also do ,not wholly to the world's benefit, perhaps, and yet with greater gain than loss.

Real Reform Through the Children

Child life in France is on the eve of a reformation. It is hard to interest French youth over ten years of age in American ways of exercise and outdoor life. Not so with the children. The French public school child is going to adopt American and English ideas more and more. He is a dear, sweet, enthusiastic little chap, full of courtesy inborn, very simple, yet sometimes living fully up to the concepts connoted by the term "gamin"; but he is France's hope and the French publicist is well aware of it. Going up and down in some little place hidden away in a valley of the Vosges mountains, we used to notice the children. "There is a husky one," we would say, "these French kids are just as strong as any other kids." But then there might be an occasion to cast a glance at a school. There, in the aggregate, was a clear showing. There one could visualize the problem; for adenoids, bad teeth, imperfect development, rickets, defective eyes, and general results of poor nutrition were often evident. Moreover, in places where one could arrive at a rough sort of child census by means of our American clinics or crèches, one could learn of the enlarged glands, improper infant feeding, the swaddling of babies, with consequent obstruction to free development, the abscesses, the imperfect hearing and sight. Of course much of all this was due to the privations and cruel hardships imposed by the war; but plenty of it is amenable to cleanliness, ventilation, drainage, and restriction and control of body discharges.

The small town laundry—that big, substantial stone or concrete tank with its goddesses, the laundresses—provides a ready means of distributing disease, for its overflow runs down the streets and through the town. It seems usually to be placed at a point which will insure a thorough partition of its benefits to the entire village, has apparently been there for time immemorial, and will be there when Gabriel blows his horn. And the small town manure piles, ranged before the houses like family altars, are tremendous fly-breeders. The manure is hauled to the fields in the spring—some of it is. Some of it always isn't, leaving a generous nidus and refuge for the perennial fly, God bless him.

Northern France, except for a brief summer period, is all water,—rain and mist above, the ground a sponge, the streams usually beyond their banks. Yet the potentialities! Not all the children were pale. The peasant-soldier is tough and hardy, the peasant-woman strong and studry. What would not good hygiene accomplish! And yet there is another side of the shield, there is the question of immunity as contrasted with, if not opposed to, the palliations provided by a too fervid worship of the padded life.

Great and constant was the exposure inseparable from war conditions. One must fare forth in cold and wet, go to bed in cold storage, and rise amid bleak airs. Yet many of us were never so well as during the days when we were ministered to by a minimum of hygiene. Never were skins so free of eruption, never was "pep" so active, never was life so joyous and so merry. An American medical officer who had had occasion to note drinking-water practice among French as well as among American soldiers told me that the French "eau potable" was harmless to the French, while the dainty overseas doughboy would be made ill by it, so that chlorination was always necessary for the Yankees' little insides. Again, is it the question of immunity, of developing resistance? Hygiene is of unquestioned necessity, but the toughening process should accompany it.

Reverting for a moment to the young people, it is remarkable how readily the French school child adopts American ideas of exercise. He is perfectly capable of learning teamwork in athletics, a thing which it is very hard to teach the present-day French youth who is beyond the ear-

lier school periods. The French youths engaged in baseball offer to our eyes a spectacle which is instructive because of its conspicuous lack of our essentials, which are often forgotten by the bleacherites because of their elementary nature. The French are excellent at football and boxing. The step of the French soldier is quick and effective, a good ground-getter. The Foyers du Soldat, a young organization modeled somewhat after the Y. M. C. A., is modifying its wartime functions to meet the needs of civilian life, and associated with it are a few American athletic directors engaged in developing hygiene and athletics for the school children and youth. The outdoor principle is a coming one in France, to which a great central stimulus will be imparted by the immense Pershing stadium erected in Paris. Athletics for girls and women are little developed as yet, but a humorous article in a French daily shows that basket ball and the Porte Maillot, one of the outside barriers of Paris, are becoming linked inseparably in the French consciousness.

This happy child hails from Parthenay. The French have not yet learned the value of free kicks for babies.

In my experience, the French diet contains too much nitrogen. Too much meat tends to constipation unless one is engaged in vigorous muscular exercise. Even then, the excessive quantity of nitrogen is suitable only for the young and still growing person.

A few health hints, roughly outlined for the benefit of the American in France, were as follows:

Attention to the bowels is very important.

Plenty of water is to be ingested.

Vegetables are to be washed in sterile water.

Clothing to be warm; feet to be kept warm and dry.

Bathing prescribed according to opportunity, a dry friction rub to serve in place of the bath when necessary.

Clean, dry underwear to be put on in the morning, frequent changes assuring an air bath to the garments.

Fighting flies should go on all the time.

Cleanliness in the environment is to be maintained as thoroughly as possible.

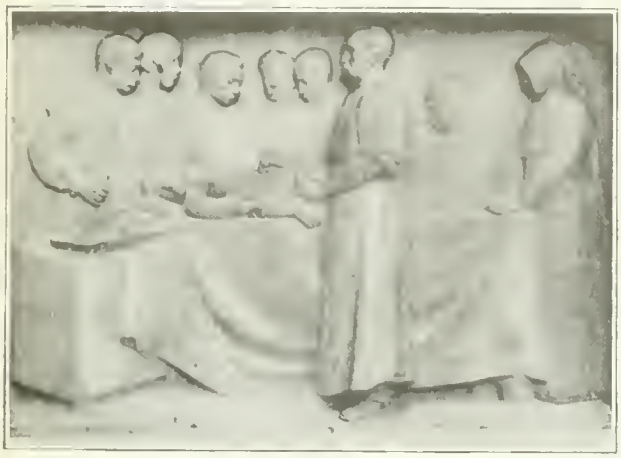
Refuse is to be burned or buried, and no accumulations of it to be permitted.

To these suggestions, even at the risk of repetition, should be added the rule of scrupulous care in the disposition of body discharges. The casual methods commonly seen in rural places the world over are likely to be lethal when made the rule for years in the vicinity of one's house and hearthstone. Uncovered holes and other lax ways which permit flies to make free journey between excreta and the exterior and interior of the body, with food as a convenient medium and halfway house, are sure to cause sickness and death which are readily preventable. The French admit the principle. With them, as with us, the difficulty lies in making theory one with practice.

Sanitation of the French railway is likely to come as something of a shock to the American novice. It must be remembered that French trains are usually intended for short runs. This principle under war and post-war conditions referred primarily to distance, leaving time out of consideration. The result was often much embarrassment and distress. One soon gets accustomed to the one and only toilet for man, woman, and child that is the invariable rule on trains where toilets are available at all. This is the case in carriages, or coaches, having a corridor or passage along one side, or practicable from and through compartments to a toilet in the end of the carriage. A toilet always exists in the express and long distance trains, at least in the first class, and usually in the second class carriages; but the local trains and the third class may and often do consist only of transverse compartment cars with no toilet whatever. A man can usually drop out for a few minutes during a stop and, between the carriages, find relief. With women, however, it is a difficult, not to say harmful, matter on a protracted, dragging trip, during which it is impossible for them to leave the compartment without a publicity which the French themselves do not seem to admire, however lightly they may take such matters in other situations.

All rules were suspended during the war. During the period of restoration, which will be so slow and so difficult, conditions will be generally far, very far, from the ideals and reals of our comparatively comfortable American life; but France will meet her necessities, will prove to be the same resourceful and ingenious nation that she

has always been. She will emerge, too, a changed nation, a nation which has learned the value of travel and a nation which will place herself on record as a practitioner of what she preaches, as well as a producer of scientists like Pasteur, Roux, Calmette, Landouzy, Hayem, and so many other brilliant members of the family of medical stars. For a national and practicable hygiene she must



The doctor is highly esteemed in France. Bas relief, monument to Dr. Chinieux, ex-mayor of Limoges.

The always-ready milk supply. Asses' milk hasn't much vogue in America, but French people use it considerably.

modify some of her political hindrances, to which Dr. Carrel is said to have referred at the moment of quitting France for return to our shores, just as we must abolish some of our own stumbling blocks if we are to progress toward a restored national life of commerce, industry and advancing human effort.

It is impossible to close without reference and tribute to a very important agency in the dissemination of a modern national and international education in hygiene, namely, the council on health and hygiene assembled at Cannes last spring under Red Cross auspices. Heartily promoted by the French, it is impossible to imagine that the counsel of the disinterested and distinguished medical men there assembled will not be heeded. The work so initiated is slowly going forward, without much outward evidence, but with far reaching effects.

Ultimately it is sure to prove a force that will be perhaps more efficacious that any other in creating an international entente and concerted action in mankind's war against social and personal pathology.

GENERAL WOOD FAVORS NATIONAL DEPARTMENT OF HEALTH

In a speech recently before a body of physicians and surgeons at Battle Creek, General Leonard Wood advocated the establishment of a National Department of Health with a medical man at its head as a member of the cabinet.

"What we need in this country," said General Wood, "is a sound national department of public health, a health bureau with a medical man at the head of it as a member of the cabinet. It doesn't make any difference who establishes it. It is a thing that is bound to be done. Our public health service is now scattered through a dozen different departments under as many different heads. What we need is one centralized department, nation wide in scope, to take care of all national problems of health and sanitation.

"The average layman doesn't realize what great advances have been made in the medical profession in the past few years. I do not suppose in any war in history medicine and surgery have done as much as they have in the late war.

"You can do a great deal under the dramatic stimulus of war, just as we did in Cuba. There we had to rid the army of yellow fever and so great was the pressure that we were justified in trying out our theories upon human beings who volunteered, and, fortunately, only one or two of them died. Out of that however, came the control of yellow fever and the control of malaria. The British had given us the first experimental work in that direction and then came the work of that wonderful American Commission, Walter Reed, Lazear, and Carroll, on yellow fever and its control. That commission saved us more lives and money every year than the war cost us and it is a possession which is everlasting. It has aided in making the tropics and semi-tropics safe for white people for all time.

"Then again we took hold of the Panama Canal, and it was built on the sanitary foundation laid in Cuba. The work of Walter Reed and his associates in Cuba made the work of Goethals and his associates in Panama possible. Delesseps and his French associates were just as good engineers as we were; they were quite as resourceful, and just as brave.

"We have no monopoly on any of those qualities; but they could not build the canal because they could not stand the terrific death rate. General Goethals, the engineer, went in hand in hand with General Gorgas, the sanitary expert.

"The sanitary methods of the medical profession have worked tremendous benefits for humanity. In fact, it was the work of medical men in very large part which made it possible to maintain a fighting force on the lines."

A PLAN TO STIMULATE THE FAMILY PHYSICIAN IN THE DIAGNOSIS OF TUBERCULOSIS

By J. J. MOORMAN, M.D., St. Anthony's Hospital, Oklahoma City, Okla.

IN Opening the discussion of this subject I desire to make a broad denial of the charge of ignorance concerning the diagnosis of tuberculosis on the part of the family physician. While it is true that to become expert in the diagnosis of diseases of the chest is a most difficult task, and that few physicians attain any marked degree of skill in this direction, the fact still remains that the average physician knows much more about the diagnosis of tuberculosis than he is credited with. His failure is due to a lack of application rather than a want of knowledge. He fails to make practical use of the diagnostic means at his command.

INTEREST DEPENDS ON CONTACT

The Medical Field Secretary should serve to connect the interests of organized health activities with those of the isolated physician who must cope unaided with the problems of the individual patient.

The scientific care of any disease depends upon accurate and early diagnosis. Accuracy of diagnosis depends upon a consideration of all the factors. Here, as elsewhere, interest is the basis of good work.

Interest in specialties and refinements of technic is largely a matter of contact. Hence the value of tying up individual and collective activities and planning an intelligent campaign to which all contribute.

Factors Contributing to Neglect

This negligence is usually due to indifference which in each individual case has grown out of one or more factors that contribute to the sum total of diagnostic inefficiency. In some instances it is due to lack of education and experience; in others it may be the result of pure laziness; but in the great majority of cases it may be more properly attributed to the urgent demands placed upon the busy practitioner. He too often yields, perhaps unwittingly, to the flattering appeals of his numerous patrons and the natural desire to crowd as much work as possible into a given period of time and thus, under the stress and strain of a so-called successful career, he leaves off one by one the diagnostic refinements and in so doing he helps to bring upon his profession the charge of inefficiency and the widespread feeling that the physicians need to be educated in the diagnosis of tuberculosis. Another factor which is worthy of consideration is the feeling on the part of many physicians who live in rural communities that their environment and lack of facilities fully justify all their diagnostic shortcomings.

The average man in the practice of medicine is prone to magnify his limitations and minimize ern laboratory methods of diagnosis have had something to do with this feeling, especially among those who are removed from medical centers and laboratory facilities. The influence of the laboratory in the progress of medicine should have full recognition. The research laboratory should be welcomed and generously supported. The diagnostic laboratory should be made accessible to as large a number of the profession as possible, and it should be freely employed as an aid in diagnosis and for the purpose of checking physical findings.

There has been a tendency on the part of some physicians to depend too implicitly upon laboratory diagnosis. We should bear in mind that while in many cases the laboratory findings are quite definite and must be accepted as conclusive, in others they are open to question and should be accepted only when they correspond with the physical findings. Let us never forget that we have ever with us all the necessary means for the application of the fundamental methods of physical examination which, if carefully and faithfully applied, will in the great majority of cases lead to a definite diagnosis, or at least suggest the course of laboratory procedure advisable in any given case. It is well for the doctor who laments his limitations to ask himself the following questions:

Have I realized fully the importance of a carefully taken history and the necessity of a thorough physical examination with the patient's clothing removed? Have I learned perfectly the topography of the normal body in order that I may the better recognize departures from the normal? Have I mastered the fundamental methods of physical examination? What degree of efficiency am I getting today from inspection, palpation, percussion and auscultation? Is it not true that those men who have stood preëminent in the field of diagnosis have done so because of

superior cultivation and application of the special senses employed in physical examination and not because of laboratory or mechanical aids to diagnosis? Have I considered carefully Sir William Jenner's notable statement, "More mistakes are due to want of examination than to want of knowledge"? Have I persistently striven to perfect myself in the application of the diagnostic means at my command, and if not, to what may I attribute this negligence? We must strive to bring these questions home to each individual physician, we must seek to develop a diagnostic conscience which will not brook the slipshod methods characterizing the past.

A Plan of Cooperation

In Oklahoma we are seeking a practical way to interest the largest possible number of physicians in the diagnosis and treatment of tuberculosis. The following plan has been suggested and in part adopted:

The State Tuberculosis Association, with the cooperation of the State Commissioner of Health, shall employ a Medical Field Secretary. It shall be the aim of the Association to secure a man of outstanding character and personality, who will command at once the respect and confidence of the medical profession. He should possess a broad knowledge of general medicine and in addition he should have special training in the diagnosis and treatment of tuberculosis. It shall be the duty of the Medical Field Secretary to study the local tuberculosis problems and their relation to other health questions and go into the various communities of the state, making himself acquainted with the physicians, meeting with them in their regular medical gatherings, arranging for special meetings for the discussion of tuberculosis, and providing for free diagnostic clinics where known and suspected cases may be examined, always in the presence of the attending physician, in order that diagnostic methods may be taught and their relative importance properly emphasized. He shall also be available for expert consultation in those cases where it is not practical or possible for them to attend the clinic.

Through this method the discovery of new cases in the community and the confirmation of the diagnosis in many of the suspected cases will tend to arouse the personal pride of the local physician and stimulate him in the use of all available diagnostic facilities. Through his close touch with the physicians and the message he has to deliver, the Medical Field Secretary may be able to furnish an inspiration which is so sadly lacking in the lives of many physicians, and which is often one of the determining factors in the making of a diagnostician.

Under the proposed plan, each state sanatorium should become a school for doctors as well as for patients. These institutions should be well equipped for diagnostic work and the medical chief should be thoroughly qualified to teach the diagnosis and treatment of tuberculosis and his staff should be chosen and organized with this in view. Provision should be made to accommodate visiting physicians and from time to time, as occasion arises, a regular course of instruction should be given to as many as can be induced to visit the sanatorium for this purpose, classes being formed as often as available material demand. While laboratory methods should be taught, the course should deal chiefly with the fundamental methods of examination which may be easily employed at home and every effort should be made to impress the importance of a carefully taken history and a thorough physical examination.

The Medical Field Secretary should be in close touch with the work of the state sanatoriums and should be on the teaching staff and participate in the work of the same when circumstances will permit. In this way he will serve as a link between the state sanatoriums and the family physician. He will be prepared to present the merits of such a course and through his work in the field the most suitable material for classes may be gathered. Such a plan would not only stimulate the physicians of the state in the diagnosis of tuberculosis, but it would insure a more scientific management of the state sanatoriums and it would strengthen the bond between the sanatorium patient and the family physician, and prepare the way for more successful and more satisfactory after-care

During the patient's stay in the sanatorium the family physician should receive monthly reports dealing with the progress of the case and the methods employed. These reports should be brief, but comprehensive, giving the various steps in the management and the reasons for the same; always emphasizing the fact that even the management is to be guided by the physician's diagnostic acumen.

The execution of this plan should in no way interfere with the usual publicity and educational activities of the Oklahoma Tuberculosis Association, but should rather increase this work, as the various phases of such a scheme should be fostered by legitimate publicity.

Cooperative Medical Society in Belgium

Cooperative stores for the benefit of physicians, pharmacists, midwives, veterinarians, and others in similar professions for the cooperative purchase of all kinds of goods have been founded. Such cooperative stores have already been organized in Brussels, Antwerp, and Liége.

THE KANSAS HEALTH CAR "WARREN"

By FLORENCE BROWN SHERBON, M.D., director, Division of Child Hygiene, State Board of Health, Topeka, Kas.

THE Kansas Health Car, Warren, has just completed its fourth yearly itinerary. In view of the present interest in graphic methods of giving health instruction, a description with an appraisement of the work may not be amiss.

Fig. 1. The aim of the health exhibit carried directly to the people by the health car, Warren, is to make its message intelligible to a fifth grade child, and to give him a unified health story.

In 1915 the Pullman Company presented an old observation Pullman car to the State Board of Health. An appropriation was made for remodeling and equipping the car, and a small maintenance appropriation has been made for each succeeding year.

The car was named in memory of the promising son of Dr. Crumbine, secretary of the State Board of Health, who died in China in 1916, at the early age of twenty-four.

The car has made one round trip each year, going over a different road each time and making, roughly, a loop into each of the four corners of the state. The car has traveled over the Sante Fe, the Union Pacific, the Missouri Pacific, and the Rock Island. It now remains to make a series of shorter trips reaching remaining portions of the state. The railroad companies have given splendid cooperation by making minimum charges for mileage and service. In addition to this, local agents and all other railroad employees have been uniformly helpful and cordial.

A Personnel of Three

During the first two years the car was operated by two Public Health Nurses and one helper. One of these nurses was contributed by the State Tuberculosis Association. Lack of funds prevented the continuation of this arrangement, and for the past two years the car force has consisted of a woman physician and one helper. This helper has been sometimes a student of social service, sometimes a nurse, sometimes just a capable woman.

The two rear sections of the Pullman were converted into tiny living quarters, as it is often impossible to secure satisfactory accommodation outside. As many conveniences have been installed as the restricted space will permit. The wiring of the car is such that it is always possible to attach to the city circuit where there is one. This makes it possible to use a grill, fans, and so on. The workers usually become quite attached to the "play housekeeping" and prefer living on the car to going outside.

During the first three years the car stopped at almost every station and the length of the stay varied from one day to two weeks, according to the size of the place. This year the cost of mileage and moving was raised and it became necessary to limit the stops to towns of five hundred population or over, and the length of the itinerary was also shortened. It has made two small towns or one large town each week.

Features of the Exhibit

The car is fitted with four long exhibit tables with built-in cabinets underneath for literature and supplies. On these tables are arranged various graphic exhibits and several chart racks. A row of charts hangs on a level with the adult eye. The curved space above the tops of the windows is also filled with charts.

The exhibit is arranged by subjects as follows, beginning at the front entrance:

Left Hand	*Right Hand*
Foods	Tuberculosis
Teeth, tonsils, and adenoids	Communicable diseases
Child care	Homemade playground
Play	Exercise and posture
Venereal disease	Infant and prenatal care
Sanitation	Examination quarters

The accompanying photographs will give an idea of the detail and arrangement of the exhibit.

Method of Operation

Advance publicity is secured by letters written to the mayor, city and county superintendents of schools, a leading club woman, health officers, and newspapers. These letters explain the purpose of the car, give the itinerary, and solicit cooperation. Data are furnished for newspaper publicity. On the arrival of the car attractive framed posters are placed in the store windows.

The General Program

On arrival, a citizens' committee usually visits the car and proffers assistance. In the absence of this courtesy, the car staff telephone the individuals who have responded most cordially to the correspondence.

A conference of leading citizens is usually held on the car the first evening of its stand. The local situation is

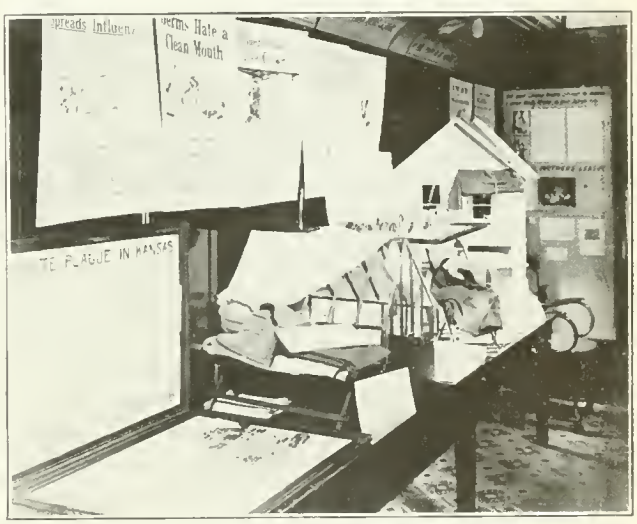


Fig. 2. The objective appeal of the model open air sleeping quarters finds immediate response on the part of the children. Graphic charts promote hygienic habits.

discussed and it is determined how the car can best serve this particular community. Usually it is arranged to hold one or more public evening meetings. A speaker or a film may be sent from the State Board of Health for this purpose. Sometimes the car physician is invited to speak at regular club meetings. Ocasionally it is arranged to open the car for an evening and explaint the exhibit to business men and others who cannot conveniently visit it in the day time.

The superintendent of the schools is always instructed by correspondence to send the school children by grades in charge of their teachers. Each grade spends one school period; the forenoons are reserved for the schools. The exhibit is explained and usually all the children are weighed and measured. When time and the size of the groups permit, the mouths are also examined.

The curved space at the top of the car is filled with charts. The car is fitted with four long exhibit tables, and health pamphlets are distributed to those who desire them.

The afternoon is open to adults and mothers with children of the pre-school age. A special effort is made to examine these children and confer with the mothers. The car physician takes care of such examinations while the assistant explains the exhibit to other visitors.

A great deal of free literature is distributed, discrimination being used to place it in the hands of persons evidently interested in the various subjects. A table is set with an assortment of books helpful to mothers. A pad of paper and pencil invite the taking of title and publisher.

What Has Been Accomplished

(1) *Community Awakening.*—While this is always an intangible thing and due to a complexity of causes, the fact remains that in various communities leading citizens have said that the visit of the car crystallized community initiative to the extent that some worth while thing followed. In one town a school nurse was hired, soon followed by a community, and later by a county nurse. Nn a number of communities public health nurses soon followed in the wake of the car. Projects in community sanitation, recreation, better quarantine, better public health service, and better school hygiene were distinctly furthered by the work of the car.

(2) *Individual Help to Mothers.*—The car affords an opportunity for many mothers to get help with their individual difficulties which they otherwise could not get. Many instances of pathetic ignorance on the part of mothers and tragic handicap to their children come to the car. Parents sometimes drive many miles to get this coveted advice.

(3) *The Instruction of the Adult Public.*—One of the most stimulating experiences which comes to the car worker is the satisfaction of hearing some farmer say while looking at the soil pollution exhibit, "Well, now. I believe that's just what's the matter at our place. I never thought of that before." One such man refused to give his address. "I'm afraid you'd come out and see my place if you knew where I live, and I sure would be ashamed. I want to beat you to it and get it fixed up."

School directors stand about the rural school bubbling fountain and the sanitary privy and discuss improvements. The miniature septic tank is a never ending source of interest to rural householders, and the indoor sanitary toilet to their wives.

(4) *Help for the Children.*—The great work of the car is with the children. They grasp everything—personal, school, and community. They go home and bring their parents. Now and then a school child will go home and bring back a little brother or sister for appraisement.

The value of milk to eke out an insufficient dietary, and its place in the food of a growing child are emphasized by this story of its equivalent in other foods.

An object lesson in training. Good health, the right environment, and directed activities take care of the future citizen. The children are always eager, alert and interested.

Individual difficulties may be brought to the car and there is interested eagerness to receive the coveted advice. In matters of general sanitation, the people are told what is wrong and wherein lies the remedy.

One of the car physicians, Dr. Blanche Hopkins, says, in writing of the car, "We found children most enthusiastic about health work, proving that if they are given half a chance they will become Modern Health Crusaders and sanitary police. I believe that health work properly presented to school children will do more to clean up a town in a month by inspecting food supply, disposal of garbage, and such agencies, than all the laws and regulations a town council can pass in a year. A few examples of the children's enthusiasm are as follows: We were discussing flies and manure piles when someone broke out, 'Manure piles! Did you see that awful livery stable right up the street, almost on the main street?' And as I seemed to doubt, a dozen voices at once tried to describe the location. It was suggested that a committee of school children wait upon the mayor to convince him that many sick babies might result from the flies born at the manure piles, for the children had learned how flies carry disease to the baby.

"At another time, a group of children told me about their poor water supply at school. Their tank having leaked, it was resting and rusting behind the school house. The teacher had frequently reported this to her Board. We asked the children to call a meeting of the Board at the car in order that we might discuss the need of good water for the school. The children never rested for two days until they had rounded up the School Board, and then they hung around in order to hear what the Board would say.

"A few hours before we pulled out of one city a very busy merchant came to the car and said: 'My children have given me no peace day or night since this car came to town, and I thought best to come and take a few lessons in health myself. Another time a father reported that when he and his wife retired to the second floor for the night, a blast of cold air struck them. He said, 'Mercy, what is the matter up here?' His wife replied, 'Oh, nothing. They have been down to the Health Car.' Upon investigation they found the four children peacefully sleeping with every window wide open. The children had read the sign 'Sleep With the Windows Open,' and had seen our models of sleeping porches. The father considered it a good joke upon himself. We talked to the children about babies who were not properly fed and who had no chance to grow. That week the school children personally conducted a young mother and her child to the car. The child, though two years old, had never walked, due largely to the fact that he had not been fed properly.

"It was our custom to show the children the car by taking the regular classes with their teacher. We arrived at a small town on Saturday. For some reason the principal of the school had neglected to advertise the car. Saturday being a holiday, it was impossible to reach all the children. The ten year old son of the mayor, evidently well schooled in civic duties, took upon himself the task of advertising the car. He came at intervals, carrying one or two on his bicycle, several children bringing up the rear. We taught him how to measure and weigh. With an assistant he wrote down the amount of any child under weight. When he found one under weight, he promptly said, 'March over to the doctor, open your mouth, and let her see what is the matter with you.' All day long this little fellow worked, bringing relays of school children. The parents realizing the enthusiasm of the children, came out in the afternoon to see the exhibit.

"Toward the latter end of the last trip of the car, the physician asked the teachers to have the children write up their visit and let her read the papers. These papers

were most suggestive—a couple, selected at random, are appended. These papers have given the State Board of Health an inspiration for remodeling the exhibit before it starts out again, with the purpose of placing greater emphasis on positive health concepts. More dolls, more miniatures, and graphic models will be used. The aim will be to make the major part of the exhibit self-explanatory to a fifth grade child, and give him a consecutive and unified health story.

By a Fourth Grade Boy

This was a health car. Dr. Crumbine sent it out into the state of Kansas to prevent people from getting diseases. We should get plenty of fresh air by sleeping on the porch and leaving your window open at night so we won't get tuberculosis. I do not want to have tuberculosis. The germ might live in an old dirty house. If we let tuberculosis go too long it cannot be cured and if you eat healthy foods and get plenty of fresh air and right kind of exercise it can be cured.

We should breath through our nose. If we breath through our mouth it will make our teeth crooked. We should wash our teeth to get all the food from out of between our teeth. We should be careful of the water because it may have germs in it.

A well should be placed on a high place because the germs won't get in the well. Toilet should be screened with wire. Flies carry many germs. We should poison a fly. Milk is our best food. Our food should be clean. We should eat less meat and more vegetables.

You should keep your body warm in the winter.

By an Eighth Grade Girl

The second week in December the Kansas Health Car visited Goodland. On December 11 the boys and girls of the seventh and eighth grades were permitted to visit it.

Upon entering the car you are under the impression that you are visiting a display of doll houses. But they are miniature tuberculosis cottages. They show how those afflicted with this terrible disease should live. In these houses or on the porches were miniature cots, such as tubercular patients should sleep on. Fresh air, nourishing food, and rest are the best cures for tuberculosis. A map showed the number of cases of this disease in Kansas. It was very strongly impressed on us that tuberculosis is a curable disease and a preventable one.

We passed on and were warned as to the danger of the many contagious diseases. We learned that there have been many more deaths from measles than from scarlet fever in Kansas, although scarlet fever is much more feared. People do not use enough precaution with measles, or other diseases that are catching.

On the other side were foods both helpful and injurious. One thing which attracted our attention was a quart bottle of milk which had ribbons fastened from it to different plates of meat, to show that one should get as much nourishment from one quart of milk as from all these meats.

We then saw where they had displayed best amusements and comforts for children and babies, also proper clothing for babies. Two babies were examined while we were there, which was very interesting. One very economical thing was a baby carriage made of two clothes baskets. One is used for the carriage and another is cut in two and half used for the hood. It was enameled white and lined and was very neat and comfortable looking. Almost anybody could make one.

There were many other things of interest such as proper sewerage and other health problems.

We were then weighed and found we have one perfect girl and one perfect boy in our class. I was four pounds too heavy.

Everyone I am sure enjoyed their visit to the car and received a great deal of good from it.

Referendum on Chiropractic Measure

A petition has been filed in California to place upon the ballot an initiative measure creating a chiropractic board and providing for the licensing of all chiropractics practising at this time. The measure will be voted upon at the next general election, November, 1920.

MEDICAL PROBLEMS IN PENNSYLVANIA

Defects are largely correctable if treated in time, says Dr. John B. McAlister, in the January issue of the *Pennsylvania Medical Journal.* Health work should begin with the children whom we force to become educated but allow to become physical unfits because good education is compulsory, while good health is optional. When the public understands how diseases may be prevented, health laws will be revamped and they will be enforced.

Dr. McAlister considers the expenditure by the State of Pennsylvania of $10,000,000 annually for the care of its dependents and the treatment of sickness as a colossal waste made necessary largely by the neglect of sickness and its consequences. Hospital care is inadequate and badly distributed. The cost of ward beds is beyond the means of half the employees of the state, and 900,000 persons in a single year seek free dispensary treatment in Pennsylvania. The organization of the medical profession for the state and correction of the sickness problem Dr. McAlister considers the most crying need of the time.

CONGRESS ON MEDICAL EDUCATION AND LICENSURE

A three day session of the Annual Congress on Medical Education and Licensure was held under the auspices of the Council on Medical Education of the American Medical Association, in Chicago, in March, with about two hundred fifty delegates present. A well arranged program was presented, symposiums being arranged on the several subjects to bring about ample discussions. "The Needs and Future of Medical Education" was introduced by Dr. George E. Vincent, president of the Rockefeller Foundation, New York City. Dr. Walter A. Jessup, president of the State University of Iowa, Iowa City, presented the subject of "The Larger Function of State University Medical Schools." "Research in Medical Schools" formed the contributions by Dr. Oscar Klotz, professor of pathology, University of Pittsburgh, School of Medicine, and Dr. G. Canby Robinson, dean, Washington University School of Medicine, St. Louis.

The subject of medical licensure was presented by Dr. David A. Strickler, president of the Federation of State Medical Boards, Denver, Mr. Francis W. Shepardson, director of the Department of Registration and Education of the State of Illinois. Dr. Louis B. Wilson, director of the Mayo Foundation, Rochester, Minn., and Walter L. Bierring, secretary of the Federation of State Medical Board, Des Moines, Ia. discussed graduate medical instruction. There were reports on the teaching of premedical sciences, the program on the whole providing the best conference that has hitherto been arranged.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

ORTHOPEDIC NEEDS OF CLEVELAND

THE hospital and health activities of Cleveland have been the subject of a recent survey for the purpose of determining to what extent, individually and collectively, they meet the existing needs and of discovering how the usefulness of present institutions may be extended by "reasonable changes either in the division of labor with other institutions, the volume of work done, or the methods of hnadling the work."

The survey involved at estimate of the needs of the city for the care of certain classes of sick. Such a study would include as well as a more or less extensive study of the community in order to determine the normal needs and to outline the character and functions of the institutions that would best serve the city.

The pressing need of more specialists and more specialization in orthopedics was pointed out at a recent meeting of the Cleveland Hospital and Health Survey by the Director, Dr. Haven Emerson, former Health Commissioner of New York City.

Dr. Emerson says there is immediate need for an orthopedic or reconstruction center in some central location in Cleveland. In addition to central social service facilities for cripples this center should provide a brace shop for the service of all hospitals and dispensaries in the city and a physical training department to which orthopedic and other patients needing physical training methods can be sent. This orthopedic center should contain a central information bureau, a social service department, an admission bureau for distributing patients to convalescent homes, an employment agency, vocational training, offices for headquarters for transportation of patients, offices from which home industries for cripples are directed, and an officer for the administration of artificial limb funds. A Department of Physiotherapy will be needed to take care of special developmental exercises for cripples, muscle training, and massage.

The second great need of Cleveland, as seen by Dr. Emerson and the Survey, is a great convalescent center for cripples. It is planned to set up this through an enlargement of Rainbow Hospital in the suburbs of the city which is already used on a small scale for crippled children. All the hospitals will direct their convalescent patients to this center. The hospital will be planned with beds for the following convalescent cripples: 150 children, twelve years of age and under; 100 adolescent and adult males; and 50 adolescent and adult females.

Resident orthopedic medical service is to be provided at this center with which the orthopedic surgeons of the different Cleveland Hospitals will cooperate. The Survey has brought together the orthopedic surgeons of Cleveland in an orthopedic council to be created under the Association for the Crippled and Disabled. The administration of the entire program is to be under the Association for the Crippled and Disabled.

Dr. Emerson pointed out the great need of orthopedic specialization. He said that "orthopedics as a science, is in its infancy in Cleveland, there being a scant half-dozen of specialists limiting their practice to orthopedic service, whereas there are forty prominent specialists in the city of Boston in active practice."

The means for such a program are provided by the Community Fund, the campaigning organization which has financed private social and hospital service in Cleveland. The matter of capital account for buildings and other equipment will be taken up by the Community Fund. The direct control of the Hospital Survey is under a committee of the Hospital Council, Mr. Howell Wright, Executive Secretary of the Council, acting as secretary of the Survey Committee.

WOMEN IN INDUSTRY

(By Our London Correspondent).

At the British Sanitary Congress, held at New Castle-on-Lyne in the late summer of 1919, many problems of great importance relating to industrial hygiene were exhaustively discussed. Sir Thomas Oliver, M.D., the president of the Section of Industrial Hygiene, passed in review the numerous advances in sanitation and hygiene which have rendered the lot of the manual laborer, the tender of machinery, and the artisan, not only tolerable, but even comfortable.

In this connection a digression from the actual subject in hand may be made to lay stress on the fact that, so far as money earning capacity is concerned, the worker with the hands is in an enviable position at the present time. He earns large wages and is not compelled to, or rather does not, as a rule, expend much of the money in keeping up social appearance. His position now is in direct contrast with that of a member of the group designated in England as the middle class, and who now are really poor. The professional classes earn little or no more than formerly; taking into consideration the depreciation in the value of money and the high prices, they are worse off, and custom has ordained that they must, what is called in the United States, "put up a good front."

Discontent a Natural Reaction

However, because the working man and woman are better paid, and properly so, does not mean that every effort should not be made to render the conditions under which they work healthy and congenial, for it is a self-evident truth that the healthy, contented worker is a valuable asset of the country in which he lives and that much of the social unrest and discontent which is such a conspicuous and unfortunate feature of the times in which we live is largely due to unhealthy and distasteful conditions of life. A economic—even more than economic—a public health problem of the first significance with which we are confronted is that of the status of woman. Long before the war, and in England in particular, woman was asserting herself in every station of life and was claiming the right to be placed on an equality with man. The war brought her into special prominence. In many respects during that trying period she may be said to have proved the justice of her claim. It is likely, nay certain, that without the aid of women the war would not have been won by the Allies. Therefore, the only part of Sir Thomas Oliver's very able address to which attention will be directed is that in which he deals with women's work from the standpoint of hygiene.

As Oliver says, the war has shown not only the important part played by women in munition factories and in other trades, but their ability to perform certain kinds of work for which hitherto they had been considered physically unfit.

Women Are Ambitextrous

The speaker drew attention to a characteristic of woman as a worker which does not seem to be known to the multitude and which is assuredly not generally recognized: namely, that the power of her two hands is more nearly equal than it is in man. She is not only more ambitious than her brother, but in her there is a slight predominance in favor of the left hand, attended by a greater resistance to fatigue. Although the feminine sex has always been regarded as weaker, woman from the point of view of resistance is not the weaker. Moveover, it is to be noted that the introduction of automatic machinery, reducing to a minimum the amount of skill and effort required on the part of operators, has made possible the displacement of skilled by unskilled labor and the replacement of adult male labor by that of women and young persons.

As to whether women are more liable to sickness than men, statistics gathered before the war say that after the age of twenty there was a larger number of cases of sickness per one hundred persons in women than men, but beyond the age of fifty-five more sickness occurred among men than women.

The numerical proponderance of women over men is greater in Great Britain than in any other country. Dr. Murray Leslie, a well known London physician, cast something like a bombshell into the feminine ranks when, in a lecture he delivered a few days ago at the London Institute of Hygiene, he declared that no real social rest can exist without feminine contentment and, where women form the bulk of the population, as in Great Britain, the effect of their sex preponderance seems to be almost wholly injurious and to have little compensating advantage. Dr. Leslie asserted that the disturbing factor of a large female excess in the population of Great Britain has been aggravated by the deaths in the war of men of the age group which represented either potential or actual husbands and fathers. At a conservative estimate there are now more than a million excess of females of reproductive age. According to Leslie, female preponderance has resulted in a large and increasing number of the physically and intellectually fittest women of Great Britain being forced into the labor market, while less provident women of the unskilled workers class married and had large families. The nation is thus deprived of the best potential mothers, and the birth rate is smallest in the best elements of the population.

The preponderance of women is, of course, not so marked in America as in Great Britain, although up to the time of the war there were more women working in the former than in the latter country. However, in both countries the woman question from the health and economic points of view is one the importance of which it is impossible to over-estimate.

The Disproportion of Sexes

Where there is such an immense disproportion of the sexes as in Great Britain, the outlook is far more serious. It signifies, in the first instance, that 1,000,000 women with all the strong sexual instincts cannot be married, and these circumstances must lead and have led to a great increase in the prevalence of venereal disease. Miss Norah March, editor of the *National Health Review*, speaking at a great meeting held in the London Mansion on February 5, 1920, to discuss the increase of venereal disease, said that women have been clamoring for sex equality for years, and now that she has partly obtained it, the effect is otherwise than anticipated. They have not raised the standard of morality but have descended to man's standard. There is no doubt that in this country, at any rate, the opportunities afforded women for engaging in industrial work, and thus becoming independent, will make of the venereal diseases a very grave industrial problem. While it may be an advantage from the economic standpoint that a woman should have every chance given her of earning a living by industrial work, it is by no means clear that the health of the community will benefit thereby. Industrial work is not conducive

to the rearing of healthy children and, in addition to the unmarried women, large numbers of married women work in factories. It is obvious that the children of these women are greatly handicapped with regard to their upbringing and, as healthy children are of peculiar value at the present time, better means for properly bringing up the children of women industrial workers than at present exist must be devised. The advent of women into industry is not unexpected but the economic situation has not adjusted itself as yet, and the matter of industrial hygiene is considerably complicated by the feminine flooding of the labor market.

HYGIENE AND SOCIAL UNREST

By Our London Correspondent.

The world is so topsy turvy just now and social unrest and industrial are so apparent and rampant, that one can think and talk of little else. The object of all wise and farseeing persons in Great Britain is to induce the population and especially the working classes to settle down to something like normal conditions. Mental hygiene is required by industrial workers as greatly as is physical hygiene. Mr. Grant Ramsay, speaking at the London Institute of Hygiene on February 11, 1920, said hygiene aimed at a healthy mind in a healthy body, and it would help us to understand the psychology of the times if we reverse the common conception of sanity, which assumes that all but the few in asylums are perfectly sane. The world has never been so insane as it is today. Young men and impressionable women were not affected, but all have come under the influence of the terrible strain of the past few years.

Crime and immorality are rampant and, as mental disease can be infective, the outbreak of crime should be dealt with as an epidemic liable to spread. There is good reason for shorter hours at the present time, and even six hours a day are too long for certain classes of work; but, with better organization, better feeding, better housing, and exchange in work, there is no reason why any fit man should not do twelve hours a day. That might be called intensive labor, and would require to be entered upon in the spirit of a good dinner, but it would benefit the worker himself and greatly help the country.

NEW HEALTH LAW IN NEW MEXICO

At the recent special session of the New Mexico legislature a new law was passed supplementing the Health Code of 1919, and providing for the levying of special taxes for health purposes, and for the appointment of employees by health authorities.

The law of 1919 created a state department of health with broad powers. This state body has passed regulations regarding the reporting of births, deaths, and morbidity following the model law; and, also, regulations for the control of communicable diseases, prohibiting the use of common towels and common drinking cups, prescribing methods for the disposal of sewage and outlining restrictions for food handling establishments and water supply plants The local health officers, however, were without sufficient compensation to enable them to devote sufficient time to their work. In order that they might be adequately paid, the new bill was passed by a large vote.

The campaign for this measure was conducted by the New Mexico Public Health Association. In view of the fact that New Mexico did not have a state health department until 1919, this further progressive step is significant.

An act authorizing employment of health employees and the levying of special taxes for certain health purposes:

Be it enacted by the legislature of the State of New Mexico:

Section 1.—That Chapter 85, Laws of 1919, be and the same is hereby amended by adding thereto the following sections:

Section 36.—Whenever, in the opinion of the Commissioner of Health conditions require the employment of persons in addition to county and municipal health officers properly to execute the health laws, rules and regulations in counties and incorporated municipalities of the state, the governing bodies of counties or incorporated municipalities. . . . may employ such additional employees as the Commissioner of Health shall designate and their compensation shall be paid from the county or municipal "Health Fund," as the case may be. . . .

Section 37.—Boards of county commissioners, annually, at the time of levying other state and county taxes, may, in their discretion, levy a special tax upon the taxable properly in the county, exclusive of taxable property within incorporated cities, towns, and villages not in excess of one-half mill on the dollar of assessed valuation of such property, and the proceeds thereof shall be covered into the "County Health Fund," and be used only to defray the cost of (1) carrying out the health laws, rules, and regulations within the county; (2) employment of the County Health Officer; and (3) the employment of additional employees of the County Health Officer.

Section 38.—The governing authorities of incorporated cities, towns, and villages, annually, at least ten days prior to the time of levying general state and county taxes, may, in their discretion, certify to their respective boards of county commissioners, a special tax not to exceed one-half mill on the dollar of assessed valuation of taxable property within their respective boundaries, and the County Commissioners thereafter, at the time of levying other state and county taxes, shall levy such certified tax upon the taxable property of such incorporated city, town or village, and the proceeds thereof shall be covered into the "Health Fund" of such city, town, or village, and be used for defraying the expenses of (1) carrying out the health laws, rules and regulations in such cities, towns, or villages; (2) employing the Municipal Health Officer; (3) applying towards the payment of the salary of the joint health officer appointed under Section 13 of said Act; and, (4) employment of additional employees of such municipal health officer.

Section 39.—The levies provided for herein shall not be subject to nor the rate thereof included within the provisions or limitations of Chapter 17, Laws 1919, nor shall anything contained herein constitute a limitation upon the right of counties, incorporated cities, towns, and villages to pay from general funds the expenses mentioned in this Act.

Section 2.—That it is necessary for the preservation of the public peace and safety of the inhabitants of the state that the provision hereof shall become effective at the earliest possible time, and therefore an emergency is hereby declared to exist, and this Act shall take effect from and after its passage and approval.

GENERAL NURSING COUNCIL

The first English General Nursing Council to be appointed will consist of twenty-five members who will hold office not less than two years. The members of the finally constituted Council will remain in office five years. The Act provides for the enrollment of nurses, and the General Nursing Council will define standards of training.

TOMORROW'S HEALTH—THE DOCTOR'S DILEMMA

By THEODORE J. WERLE, Milwaukee, Wis.

A full measure of medical service is required by the public and must be supplied by the profession. Its administration will differ from that of the past.

The leaven of education is becoming active. Public problems that formerly could be dealt with en masse and solved with a sort of blanket remedy now meet with an awakened public interest which requires their solution on a more scientific basis.

In the reorganization that is sure to follow no one class can rely upon precedent, or custom, or tradition to make its tenets stand; but all must interact and work out in perfect mutuality a more satisfactory organization than that hitherto achieved.

ALMOST any doctor one might approach on the subject will agree that the only logical way to treat disease is to prevent it. "But," he will say immediately after granting that hypothesis, if he is an average practitioner, "in practice it won't work out. The public will not permit it. The people are not ready to take prevention seriously."

"Can you estimate about how much money will be spent in the United States in 1920 for organized health work?" I asked a public health official the other day. After several minutes of mental calculation, he said, as if astonished by his own reply: "Why, it must run well over a hundred million."

A hundred million dollars, or thereabouts, to bring home to the American public, in one way or another, the one fact that disease is preventable represents rather a tidy little sum, and would naturally lead one to wonder whether, after all, the public is not showing a great deal of interest in preventing disease.

I am not, however, offering a hundred million dollar guess as an answer to what I have intimated to be the conviction of medical practitioners. Whether or not the sum is a hundred millions, or seventy-five millions, or fifty millions, is quite immaterial to my present purpose. The fact remains that the American public is engaged in a tremendous, and steadily mounting effort to prevent disease, an effort which for magnitude, originality, and resourcefulness has no equal anywhere. Men who should know a good deal about it are fairly well agreed that for 1920 there will be spent between seventy-five cents and one dollar per person in this country—money dedicated to teaching the principles of disease prevention, and raised from public, semi-public, philanthropic, and business sources.

The movement is largely an educational one, and is full of advertising. Health is the product advertised, and to use an advertiser's phrase, "The campaign has been pulling its head off." Therein lies the doctor's dilemma.

Medical altruistic zeal through bacteriologic research has given us our conception of the preventability of germ-caused diseases. Yet the medical men in the mass do not seem to have been following up the tremendous social potentialities of their findings. They apparently have preferred to remain primarily curative agents while disease prevention has become separate, to a degree, from the profession and dependent for its effectiveness on public approval. Today, with each disease added to those known to be germ-caused, physicians give ground from the old curative field, and yield it to prevention, a force which is now rapidly gaining the warmest public approval, and which is mounting in potential importance well over that phase of health work to which medical men as a body have been confining themselves: namely, the diagnostic and curative. In fact, when the American public becomes sufficiently enlightened to judge values in its own health problems, the curative field in public health, now the private practitioner's enterprise, is more than likely to become just a part of the great publicly owned and publicly directed preventive work; and I do not believe the day of that judgment to be more than a generation in the future.

The Physician Shall Lead Them

For leadership in this much to be desired prevention, the public has naturally turned first to its physicians. But the idea, while acceptable in the abstract, has not entirely appealed to the practising physicians when the project was to be applied to their daily business. They have been slow and unwilling to accept the leadership. There are plausible reasons for such an attitude in the physicians; reasons, no doubt, grounded in the history and training of the medical profession; which reasons, however, are not comprehensible to a people educated in the gospel of "getting results."

There is in the lay public not alone a distinct demand that disease be prevented, but a further

demand that the economics of medicine be revised to put medical service in a position to prevent it; and there is a growing consciousness in the layman's mind that his family physician and most every other physician are doing very little about it. The high cost of medical service is impressing the value of prevention on the layman, and is raising this question of economic organization of private practice. One needs to refer only to the available reports of sickness surveys to find justification for the charge that private medical enterprise does not meet the social need for medical care. Let us clear in our minds that this is not an indictment of medical men at this point, but of the scheme under which they are operating. Regardless of any defense or explanation that private practice may offer, the great charge seems to stand as a fact that upwards of one-fourth of those seriously ill enough to be confined to bed, go without medical care. Unless medicine as now organized can adjust itself to meet the challenge of the uncared for sick, the medical profession must expect the lay public to cast about for a scheme of medical service which will operate with better than seventy or seventy-five per cent efficiency.

Something Is Going to Be Done

As a lay medical worker, I have been in public health work for nearly ten years and never before have I seen more interest in health. As I watch the public in my contacts, I see crystallizing the decision that, with or without medical leadership, something is going to be done about this business of promoting health.

Within my own recent experience there have occurred several rather significant incidents. In a small city of about 20,000 population, in one of our northern states, a group of club women, known as the Health Committee of the Women's Club gathered some facts relating to disease and health conditions in their city. They decided that something should be done to reduce the cost of medical service for certain types of families in their city, families forced to go without medical care except in acute illnesses, yet families that were not paupers. After several meetings with the physicians of their county the ladies found that not alone could they expect no plan from the physicians, but they were denied cooperation by the medical society on any practical basis.

The women were convinced of the fairness of their proposal and were determined to put it through. Here is the significant thing. They did put through their plan—a public health dispensary—in face of the doctors' opposition. The public never for a moment accepted the medical men's viewpoint, and the dispensary is operating today with splendid success.

Many plans are being offered and discussed in a search for the new medical economies. I shall not presume to say what that new plan might be. One who realizes the seriousness of the situation is likely to be slow to accept or reject any plan—and these vary from private enterprise to socialism. Certainly the lay public will in the future not be satisfied to permit medical science to be so decidedly in private hands as it now is. Whether the new scheme will be a radical one, a more or less ruthless departure from the present, or a plan based on careful consideration of the demands of the profession, will depend very largely on the medical men, themselves.

Attitude of the Lay Public

I know very well that the leaders in the profession have been calling attention to the attitude of the lay public in this matter. They are aware of public sentiment, and they have counselled wisely that the only true course for the profession lies in taking the lead in the formulating of new policies; but, and I feel sure these men will agree with me, the doctors have been slow to heed the call of their prophets. In fact, if they have been heard at all, the prophets don't know it.

Although some of their own men have been sounding warnings, the recent action of a group of New York State physicians in forming what they call a Physician's Protective League to fight health insurance as a menace to the profession, is an example of the kind of reaction which will deprive medical men of the leadership in medical reform—a leadership which the public is willing they should have. The medical profession hardly seems to need a protective league; wouldn't an "Expansion League" serve better? These men are like the traffic policeman who bawls out at an auto owner, stopping his car in a restricted district, "You can't park your car there." That policeman certainly is not improving the parking situation. What the man in the automobile wants to know is where he can park his car.

Germany and England before the war gave their physicians an opportunity similar to the one now begging American doctors for helpful attention. As we know, the European medical men persisted in the attitude the New York State men have taken, and with what disastrous results. They fought the new order to the last ditch and lost all voice in the forming of the new plan, and there was a new plan.

Permit me to quote from the Annual Address[1]

1. Address by Dr. H. E. Dearholt, Wis. Med. Jour. Vol. 16. No. 5. October 1917.

of the president of Wisconsin's State Medical Society, delivered in 1917. This address was a call to the helm of socio-medical affairs. He literally begged medical men to see the great opportunity lying before the profession.

> The state of war in which this nation exists is daily teaching us new truths and giving new significance to old truths. From earliest childhood we have been taught that America belongs to the people. Some accepted the ownership as naturally and with no more gratitude nor sense of obligation for the privilege it afforded than a child commonly exhibits to his parents for the living, education, and other advantages they furnish him. It took a national campaign of education to arouse the public consciousness to the justice and rightness of the principle of military conscription—to drive home a well defined realization of the fact that the people belong to the country no less than the country belongs to the people. And right here, though not all of us have yet heard it, the death knell was struck for vested rights in the private possession of the benefits of medical science and in the privileges of health. . . . It is a short step from this point to conceive that medicine belongs quite as much in the domain of public ownership as do highways and waterways and all other forms of public property.

New Situations Arise

To a layman who works with it, and who knows it as individuals, the medical profession is an extraordinary body—closely knit by a splendid code of honor, yet sorely in need of unity. In matters pertaining to their ethics one finds very little deviation from a system universally observed; yet they rarely organize with one another to meet a situation affecting them from without. Physicians as a whole, seem to a layman to feel very secure in their profession and its standing. They seem to rest on a sense that, somehow or other, medicine will come through all right—it always has.

As seldom has happened before in their history, this campaign affecting the doctors is based on fact, not prejudice. This campaign is not directed against the science of medicine or any of its adjuncts, such as vivisection. It is directed against the present scheme of the practice of medicine. The public is dissatisfied with this scheme not for the things it is doing, but for the things that it is not doing. In other words, medical practice is much in the position of a man whose job has grown faster than he has. The man must do something pretty soon or his boss will. This is the dilemma. The test of medical men now seems to me to lie in whether or not they are going to swing up into the bigger job. Will they seek and maintain the position of leadership, as they should, in the larger enterprise, the social and economic reorganization of the forces controlling health?

Will they do as so many of our geniuses who labored ceaselessly for great truths, and when they have found them, permitted the fruits of their labors to pass them by, enriching others? Or, will they do as Thomas Edison, develop to its fullest social and economic effectiveness each new discovery of their laboratories? The vast advertising campaign of which I have spoken is directed at popularizing just that enterprise which the physician has been dodging, disease prevention. Unless he changes his attitude, the doctor will find the great power of prevention in the hands of others, while he will be its servant in one of its departments.

Physicians should not lose sight of the fact that a considerable proportion of the lay public is already engaged in some part of this marvelously complete health campaign. No merchandising scheme with its jobbers, wholesalers, retailers, canvassers, and demonstrators was ever more complete, or will reach nearer 100 per cent sales than this loosely organized, frequently overlapping, sometimes conflicting effort of the public to sell itself the prevention idea. And this fact is very clear—the idea is "getting over."

As their own prophets have called out repeatedly, medical men seem to need a more closely knit and centrally directed working organization, an organization equal to dealing with mass health problems. They need an executive secretary, as it were, one who should be able to conscript into the service of medical practice the ablest thinkers and economists in or out of the profession. Behind such leadership the profession should easily hold first position in any fundamental reorganization which the practice of medicine may be facing. These men should seek to unify the physicians behind their leaders. They should seek to reconcile the private practitioner's point of view with that of the lay public.

Many doctors see medical service only as a means of earning a livelihood. With them it is a matter of bread and butter. They are not aware of their tremendous importance in the social order. The present scheme of things meets their needs and they are suspicious of innovations. On the other hand, health and disease are to the layman a matter of life and death, not merely bread and butter. The layman feels that there are other things a doctor might do if he does not like the returns he gets from the practice of medicine, but a life once lost can not be replaced. And just now, on the doctors' own statements, too many lives are being lost needlessly. So the rank and file of medical men will need to realize that a mere standing on their present rights will not stay public demand for reorganization.

Is it not the province of the medical profession to lead the way to the new order?

LAW FOR THE DOCTOR*

By LESLIE CHILDS, Attorney At Law, Indianapolis, Ind.

Alleged Deceit and Fraud Upon the Public as Grounds For Revocation of Physician's License

In Macomber vs. State Board of Health, a Rhode Island case, reported in 28 R.I. 3, it was attempted to revoke a physician's license on the grounds of alleged conduct of a character likely to deceive and defraud the public. The case is an interesting one of its kind, and an excellent example of the varying value placed on the same evidence by different classes of men.

Dr. William S. Macomber was a physician engaged in the practice of his profession in the state of Rhode Island. In the treatment of various diseases he employed a device known as the "electricure." It seems the doctor advertised the "electricure" extensively and distributed generally the "blue book," which contained, among other things, the following statements:

"The electricure . . . absolutely cures consumption, female complaints, paralysis, rheumatism, heart disease, and all acute, chronic, and organic diseases, no matter what their name or origin. . . . It is no faith cure or necromancy, but is the practical application of the greatest discovery—the giving of oxygen—of this wise age for the cure of all human ills and all ailments of beasts as well, for the principle affects equally all living kind. . . . Let no invalid despair or seek the sea, the mountain, or a foreign shore in search of health—perchance to die—when it can be surely found at home by the intelligent use of the electricure; for cures are wrought by it that, under the old system of medication, are impossible."

The secretary of the State Board of Health preferred charges against Dr. Macomber, based on the above and similar advertisements, charging conduct unprofessional and of a character likely to deceive and defraud the public. The case was tried before the State Board of Health, the doctor was found guilty, and his certificate revoked. An appeal was prosecuted to the Supreme Court, and in passing on the evidence contained in the record the following among other observations were made.

"A number of advertisements from Providence papers relating to cures or alleged cures said to have been made by use of the 'electricure,' . . . are produced by the State Board, upon a few of which appear the name of the appellant as 'specialist,' or as 'physician in charge'; also certain circulars and advertisements purporting to explain the 'electricure,' and exploiting in glowing terms its powers in the cure of numerous diseases. It is evidently the intention of the State Board that this Court shall infer, from the language of these various advertisements, that the statements therein contained are untrue, that the claims made are extravagant, and, therefore, likely to 'deceive and defraud the public,' and that Dr. Macomber, the appellant, by allowing his name to appear upon some of them or by distributing some of them to his patients or to inquiring parties has been guilty of conduct as above set forth. Unfortunately, however, the State Board has not seen fit to offer any testimony to show that any one of the statements set forth is untrue in fact, or even that it is extravagant or misleading, or tending to 'deceive' or 'defraud the public.' The evidence is submitted to this Court as if the Court were a body of medical experts, fully qualified to pass upon all the numerous medical questions involved. It is hardly necessary to say that this Court disclaims such qualification, and cannot take judicial notice of such matters, but is bound to form its judgments in such matters solely upon evidence adduced before it. . . .

"The most cogent evidence to show that the appellant had been guilty of 'gross unprofessional conduct, and of conduct of a character likely to deceive and defraud the public,' would have been evidence from some one or more persons that he or they had been actually deceived or defrauded, had been led into expense without adequate benefit, or had been told that they would be cured of any of the various diseases mentioned, and had taken the treatment without results, or with bad results; or that the statements made as to cures actually effected were in fact untrue. The Board has produced no evidence of this character; but, on the contrary, the appellant has produced seven witnesses of apparent respectability and intelligence, none of whom are in any wise discredited or impeached or contradicted, and all of them testify to substantial relief or cure of serious disorders or disabilities. Dr. Macomber himself in his testimony shows that he did not in any instance attempt to 'deceive' or 'defraud' his patients by any extravagant claims or promises, and that he did not demand pay from them unless they themselves were satisfied with the treatment and its results.

"On the whole case, while the Board has succeeded in raising some considerable suspicion in our minds as to the matters in question, we are satisfied that the evidence is not sufficient to warrant the revocation of the appellant's certificate, in that it does not show that the appellant was guilty of such conduct as charged."

The decision of the State Board of Health was thereupon overruled. Justice Blodgett filed a vigorous dissenting opinion from which some of the facts in this article are taken.

MEDICAL MISSIONARIES

An appeal has been issued by the Interchurch World Movement for volunteer physicians for five years' service in Asiatic countries. General practitioners and specialists are desired for service in Turkey, India, China, Japan, Syria, Palestine, Siam, Persia, Indo-China, Malaysia, Philippine Islands, and in Africa. It is announced that more than six hundred physicians are needed. A salary of $3,000 and a home is offered for married physicians and $2,000 for single physicians. All traveling expenses are paid by the organization.

MORTALITY FROM INFLUENZA, 1918

The mortality statistics just published by the United States Census Bureau indicate a total number of deaths from influenza of 228,120, and from pneumonia 162,812, from bronchopneumonia 52,408. These deaths are dis-

A SAMARITAN QUARTER FOR HOUSING AND EMPLOYING THE SEMI-INVALID

By S. WACHSMANN, M.D., Medical Director and General Superintendent, Montefiore Home and Hospital, New York City; Professor of Clinical Medicine, Columbia University, New York City

THE question of employing partially disabled workers, in the majority of cases, can ultimately be reduced to the problem of either bringing the work to the cripple, or bringing the latter to the workshop. Either method has great disadvantages, which offer such difficulties in practice as to make it almost impossible to reach an economical arrangement in most instances.

If the cripple is to stay at home, some other person has to call for the material and deliver the finished work, thus engaging another member of the family with a corresponding loss of time, expense for carfare, and the necessary amount of bookkeeping, not to mention the possible loss of material, and taking it for granted that in the cripple's home a sanitary and otherwise suitable place can be found to do the work and store the material.

Specially planned houses and systematic placing of houses and factories in the Samaritan Quarter provide for the needs of the handicapped.

There are two ways to bring the cripple to the workshop: An employer may send a coach around to gather the cripples at the beginning of the work day, and send them home in the same way, as is done by some cripple schools. There it is comparatively easy, because children can readily be lifted in and out of a coach; but one need only be present at one outing given to the inmates of a home for chronic invalids to understand the great difficulties of handling adults who can neither stand nor walk. The cost alone of such transportation would exclude this method from practical use for the purpose of making the cripple a wage earner; besides, they would all have to live in ground floor apartments to avoid the extra handicap of stairs.

The other way of bringing the invalids to the workshop would be to house them in dormitories, barracks, or similar arrangements under the same roof with shops or factories. This would mean separate institutional management, which is costly and alien to commercial enterprise. Furthermore, it would deprive the cripple of family life and bring permanent hardship to him and those who are dear to him.

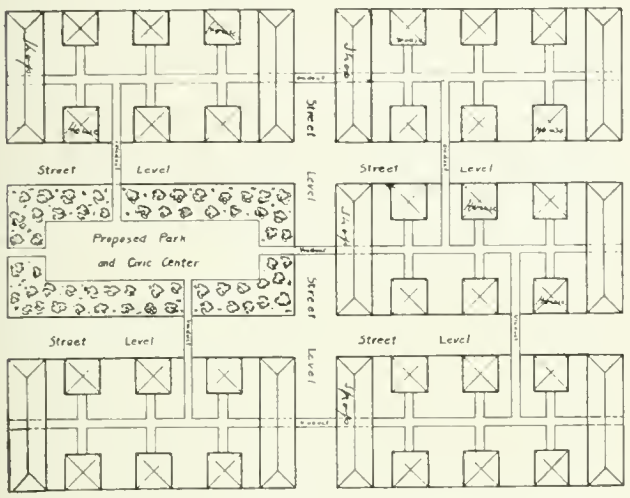
Transportation, in the great majority of cases, is the most difficult problem, because even those who can move about on crutches or with artificial legs have considerable trouble in using congested public conveyances during the usual rush hours, particularly in crowded cities. Wheel chair cripples, who have lost the use of their lower extremities, can rarely travel for any distance or cross streets, nor can they ever negotiate steps or stoops to enter into buildings. People with only one hand are hardly considered as seriously handicapped nowadays, but those who have lost both hands or arms, even with the best artificial limbs, have difficulty in traveling on public cars, while gettnig on or off, paying ing fares, etc. Lengthy traveling to and from work, moreover, is a serious matter not only for crippled persons, but also for those disabled or handicapped by disease, such as cardiacs, consumptives, rheumatics, and others.

The problem, therefore, of utilizing the earning power of the handicapped in a rational economic way can best be solved by bringing the workshop and the cripple near one another, so as to reduce traveling to a minimum of distance and discomfort, without an actual physical combination of shop and home.

To bring about such a proximity between the worker, especially the handicapped worker, and his shop, one will have to deviate from the present arrangement of dwelling places and grouping of industrial buildings. Special reservations for each city, or, on a larger scale, for each county or state, should be built according to a definite plan, which will involve systematic placing of factories or shops and, between them, houses of a special type, lined up in blocks. Smooth connecting roads for pedestrians and wheel chairs will be in the center of the blocks, while regular streets for ordinary traffic will run around the blocks, as usual, except they will be depressed to the depth of the usual viaduct, so that connecting bridges will not interfere with wagons or street cars passing underneath.

The houses will have two fronts or entrances,

one from the street and one facing the block center leading into the second story. These latter entrances will be on a level with the roads, without even a threshold, and the second story of each house will have the rooms constructed with wide doors to admit wheel chairs, also without thresholds, and the bath rooms built in the same way. The toilets might be provided with grip rails, such as are found in homes for chronic invalids or



As the unit grows, the Samaritan Quarter should provide parks, playgrounds, and places of entertainment easily accessible from all points.

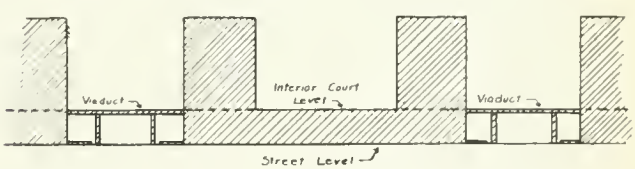
aboard steamers for the victims of seasickness. All other stories could be of ordinary construction suitable for all kinds of tenants, so that the families may remain united. From each block entrance, or better, inside entrance, a path will lead to a wide center road which runs through the long axis of a block. At either end of the block will be an individual building constructed on similar lines, with a street entrance for public traffic and a block entrance for the workers, and without steps or thresholds, on a level with the inner roads. These roads should be surfaced like the driveways in most parks, *i. e.*, somewhat roughened, fairly hard, a tar road with fine gravel, so as to make traveling easy for wheel chairs and to prevent slipping of crutches or walking sticks in wet weather.

Each such block should be a unit and the inner roads would naturally be free from vehicles. In addition to the great advantages for cripples and invalids these conditions would be ideal for children, who could go to school without the parents having to fear that they might be injured by an automobile or a fire engine. To prevent the feeling of isolation in the "block dwellers," bridges on all four sides, level with the roads, will establish connection with the adjoining block, so that the population of the whole reservation can intercommunicate and visit at will, unmolested by public traffic. There will be an elevator in each industrial building, so that the cripples can reach the street and take longer trips, if they wish to do so.

The section as described before should be known as the Samaritan Quarter or some other perhaps more suitable name. Now, right after the war, every community should open a Samaritan Quarter and maintain it. All of these people, while not in need of institutional care, can not exist or work under conditions which were intended for normal individuals. Certain modifications in the constduction of streets, houses, or factories, and an adaptation of the work benches and other equipment will enable the invalid to earn a livelihood and enjoy life almost as well as the normal person. The vocational schools and other facilities for training those who are capable of being educated to a higher level tha nthat of factory hand should also be in the Samaritan Quarter. The schools will do more good there than can be expected if they are located in a busy section of the city. Perfect sanitation, a healthy neighborhood, and good street cars or other connections are necessary, for obvious reasons, to make the Samaritan Quarter a success.

The industrial buildings would be rented to employers in various trades and the houses let in the same way, better and more easily, perhaps, than in many of the congested districts. The entire arrangement will have so many advantages that it may also attract families where there are no cripples. Thus it may help to improve the housing conditions of the working class in general.

In connection with this problem it might be



The Quarter provides smooth connecting roads for pedestrians and wheel chairs. Streets for ordinary traffic are depressed the depth of the usual viaduct.

well to answer the question whether or not it might be advisable to reserve certain industries for semi-invalids. A similar principle might be applied as that in use by municipalities in granting licenses for peddling only to handicapped people.

The financial side, of course, must be studied separately and be subjected to careful scrutiny and calculation. The plan seems so natural, however, and in no way radically different from normal real estate procedures, that in all probability the element of charity will have very little, if anything, to do with it, and the scheme will be rather a sound, self-supporting philanthropy.

ALL-TIME HEALTH OFFICES IN KENTUCKY

A number of counties in Kentucky are taking advantage of the offer of the State Board of Health to subsidize the establishment of all-time public health service. Five counties, Daviess, Christian, Scott, Boyd, and Harlan, have already taken action.

CANCER IN WORKERS ON COAL BRIQUETTES

The authorities in Germany are now collecting data in regard to cancer in persons engaged in making coal briquettes. In the last five years there have been ten cases of epithelioma recorded in a total of 2,500 workers. It was on the face or arm in five cases and the scrotum in five others. Conjunctivitis is also common among these workers.

NIGHT MEDICAL SERVICE FOR PARIS

The Prefect of Police of Paris has organized a service of night doctors for Paris, who will be available from ten o'clock at night until seven in the morning. The number will at first be thirty, to be increased if necessary. Paris is divided into five sections, in each of which a doctor is permanently on duty during the hours stated at a central police station, where a room containing the necessary accessories will be available. The call for the doctor will be made to the nearest police station by the patient. A telephone message will then be sent to the central station and at the same time an automobile will be despatched to take the doctor to the patient. Each car is furnished with a case containing first aid appliances. The medical service is so organized that the turn of each doctor comes once in six days. Labor cases will be served by the midwives attached to the night medical service; if a midwife has to resort to a doctor for help she will be able to requisition his services on the lines indicated. The charge for night visits by the doctor will be a uniform one of fifty francs, except in cases of extreme poverty.

CONFERENCE OF INDUSTRIAL PHYSICIANS AND SURGEONS

The Division of Industrial Hygiene and Engineering of the Pennsylvania Department of Labor and Industry held its Tenth Conference of Industrial Physicians and Surgeons in Harrisburg on March 25, the last day of a successful four-day Safety Congress held under the direction of that Department.

The injured in industry received attention from Dr. Harry E. Mock who presented the problem of the rehabilitation of the industrial cripple, detailing the plan of organization and the work accomplished by the Service League for the Handicapped in Chicago, Ill., emphasizing the three important points to be considered in all work with the handicapped as medical, educational, and industrial; Dr. Frederick L. Hoffman offered a plea for those injured in the course of their occupation by disease, urging the enactment of laws to provide compensation for industrial diseases as well as for industrial accidents, substantiating his arguments by reference to information just recently acquired and not yet published, on the subject of workers in granite.

Dr. C. E. Ford outlined an ideal plan for health education for the workers of our industries pointing out the advantageous relationship to the whole community of even elementary work done along this line in the plant.

The difficult problem of placing the substandard worker was most effectively elucidated by Dr. Irving Clark who classified these workers and submitted a plan whereby these subnormal conditions may be easily and quickly diagnosed and, through the cooperation of the employment department, these handicaps fitted to a suitable job.

To eliminate the malingerer Dr. Judson Fisher asked assistance from the industrial surgeon, the employer, the employee, the industrial accident boards, and the public.

Dr. C. D. Selby outlined a most complete system for the location and equipment of plant dispensaries of varying size and emphasized the importance of standard treatment as well as standard equipment.

The two disease conditions of influenza and cardiac insufficiency were discussed by Dr. Alfred Stengel and Dr. William E. Robertson, respectively. Either one of these papers in itself was well worth attendance at the conference to hear, and will be consulted for years as standards by industrial physicians.

The proceedings of this conference will be published in the near future and may be obtained on request from Dr. Francis D. Patterson, Chief, Division of Industrial Hygiene and Engineering, Department of Labor and Industry, Harrisburg, Pa.

OHIO STUDIES MORAL DELINQUENCY

Youthful offenders in Ohio are no longer to be committed directly to penal institutions, but are now submitted to the State Bureau of Juvenile Research for determination of the underlying causes of delinquency, so that proper medical measures may be employed, according to the March issue of the *Ohio State Medical Journal*. It is the belief of Henry H. Goddard, director of the Bureau, that preventive work in the detection of early peculiarities leading to bad conduct, and directing the education of delinquents into social lines are as much the function of the Bureau as assigning incorrigibles to suitable institutions. The personnel of the Bureau will include the specialists needed to render a complete service.

UNDER-GRADUATE INSTRUCTION IN INFIRMARIES

Signs are not wanting, according to *The Lancet*, January 24, 1920, of a new attitude on the part of the public toward medical education, and the resulting changes in the methods of instructors of medical students constitute a notable event in the history of medical education. An important development of this kind is the new agreement between St. Mary's Hospital and the Paddington Board of Guardians, by which the clinical material of the Paddington infirmary will become available for teaching purposes and provide valuable material for investigation and instruction in every form and phase of chronic illness, especially in diseases of the respiratory tract and in chronic heart diseases.

In the selection of cases which has been made in the Hospitals of London, it has been possible for a medical student to go through his course only rarely seeing the treatment of such diseases as tuberculosis of the spine and hip, chronic septic osteomyelitis, the palliative treatment of malignant disease, and some acute inflammatory and orthopedic conditions. Further cooperation between the hospital and infirmary should make it possible to fill a hitherto distinct hiatus in medical education by the provision of psychiatric clinics for incipient mental diseases.

Another beneficial result which is anticipated is that this wealth of clinical material will make possible a more intensive study of the beginning of disease. The gain to the public is not less marked as better facilities for study should mean better care for the sick.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

PREVENTION VERSUS REPAIR

HEALTH posters have a value in the work of prevention. In the Greater Community Hospital at Creston, Ia., a nice large room is reserved for the lecture and class work of the nurses in training. Unlike any nurses' classroom that has ever came to the attention of the editor, it contains, not only the ever present skeleton whose minutest bone is a matter of vital importance, but, on its walls, many charts and illustrations which give the pupil nurses a keen sense of the great wastage of life permitted to go on daily and a deep appreciation of the value of lectures on the causes and transmission of diseases.

These illuminating graphs and charts—simple, direct, and often accusing—are bearing fruit in the minds of the nurses in training in that hospital school. While we were copying some of the words under the graphs and pictures, a bright, earnest young woman approcahed and said: "Isn't it too terrible to think that so many of our patients need never be sick if everyone only did his part to prevent the spread of disease! When I graduate, I shall know how to care for those unfortunate victims of public carelessness when necessary, but I want, so much, to *help keep people well.* I can hardly wait until I get through my training. I want to go out and talk from every house top and tell everyone that for three years I have nursed and tended the ill and dying who were victims of their carelessness and indifference. Isn't training to be a nurse wonderful? You get such a complete knowledge of results. After nursing a very ill typhoid fever case or a tuberculosis patient, you really feel that everything you can do is little enough to prevent other people getting sick. Nursing to cure is the stimulus to prevention."

Is not this a wonderful spirit for a young pupil nurse? It is quite different from that of the young graduate who saunters forth from her training school with little thought other than certainty of a job, convenient to home or with short hours, be it a private duty case, an institutional or a public health position?

Shorn of their color and illustrations, there follow some of the charts that tend to make these young nurses think:

Preventive Medicine as a Patriotic Service

At the same rate that prevailed during the Civil War, our loss during the United States' participation in the World War would have been:

From malaria	13,915;	it was	13
From scarlet fever and diphtheria	1,299;	it was	267
From dysentery	63,898;	it was	42
From smallpox	9,536;	it was	5
From tuberculosis	9,574;	it was	1,220
From typhoid fever	51,113;	it was	213
From other diseases (men only) exclusive of pneumonia	34,881;	it was	3,768
From pneumonia	38,963;	it was	41,747
Total from all causes	223,179		47,275
Total saved	175,904		

The Greater Community Hospital

This Institution is to be the home of a service in the form of organized and sustained activities directed to the prevention of preventable disease, the correction of correctible defects, and the restoration, repair, and relief of those disabled by troubles we fail to prevent—a service dedicated to the conservation of men and women, to the protection of children, and to the promotion of their normal development.

A few facts concerning ourselves in the Greater Community are shown in the map:

As compared to averages for the state of Iowa at large, we have: more money per capita; more churches; a higher percentage of average daily absences of children enrolled and a higher ratio of insane; we expend more for the maintenance of graveyards than we do for playgrounds; and our expenditure for health departments is less than our income from the dog tax.

During the year 1915, the people of Iowa paid for state care of physical, mental and moral defectives, $4,540,571.00, which approximates two

dollars per capita for the total population of the state.

Through modern social and scientific service, at least 50 per cent of these defects could be prevented.

The economic loss from disabilities and from the discounting of human efficiency resulting from preventable disease is greater than that from fire, flood, and tempest, added to the average animal loss, hog cholera. This, too, is exclusive of the economic losses from untimely deaths.

Compulsory Education

At the age of *five* he *may* go to school.

At the age of *six* he *must*—that's all—the only specification is age.

BUT—About what should be his weight?

The kindergarten child should acquire during the September to Christmas term about one pound. There is something wrong with a child that makes no gain in weight during a school term.

If it pays to have scales in the barn yards, why not in the school houses?

Isn't there something wrong with us if the revelations of the selected draft fail to inspire reformation in our poverty of provision for conserving the health of school children?

What better service could any Red Cross organization render than that of providing Public Health Nursing Service for our respective communities?

The casue of these unfortunate features is not lack of Christian spirit nor unwillingness to spend money; neither is it lack of organizations for welfare promotion.

It is the lack of a definite plan by which our forces may be concertedly directed to the conservation of vital interests common to all.

The Greater ommunity plan offers a way.

About 60,000 school children died in the United States last year; approximately 37,000 of them from preventable disease. Southwest Iowa, no doubt, furnished its quota.

But Iowa, as a state, is thoroughly aroused as shown by the rapid growth of the Public Health nursing service. Upwards of one hundred and fifty public health nurses, including school nurses, are now at work in Iowa. How many in your county?

Is it wise business management to expend public funds in purchase of equipment for protection of property against fire, and still more perfectly good money to maintain service, capable and ever-ready people who know how to fight fire, prevent its spreading to innocent bystanding buildings; and the night patrolman and the inspector of the buildings under construction? Of course; it's good business.

Here in Creston, we have $22,000 worth of property and apparatus that are dedicated to the protection of our houses and our goods against fire. Maintenance of the service costs us annually, including hydrant rentals, about $10,000. Notice this fact: The service is obtainable by any person who may need it. The fire companies work no less faithfully to save the home of a poor man than for rescue of the rich man's mansion—all of which is good business and right in principle.

Another notable public service that involves expenditure of public money is our Health Department. The value of our equipment (municipal devoted to defending our lives and health against preventable disease since the pest house burned) is . . . well, so far as we can learn, it is expressed in the supply of our quarantine cards painted in large type, warning persons to keep out, a most beneficent provision, is it not? For services of health officer and incidentals we paid, last year, $369. Heavy, isn't it?

In this connection it is interesting to note a fact that in great measure mitigates the seeming prodigality of expenditure for protection of mere people against disease. The municipal cemetery paid a profit of $309. So, after all, we are only $60 on the account with human life and health conservation.

As beneficiaries of the past, our only escape from going on record as self-convicted parasites is to make ourselves benefactors to the future, or at least to try earnestly and persistently to make the community a better place to live in because of our having lived there.

Health Texts for Every Man

During the past 20 years, the annual death per 100,000 population has been reduced for:

Typhoid fever from	36 to 15
Diphtheria from	43 to 17
Tuberculosis from	202 to 147
Enteritis under two years	108 to 70

but the death rate from diseases incident to childbirth continues about the same.

Most of the so-called offenses against society are society's own chickens come home to roost.

The principal business of each generation of men is the production and preparation of the next.

Not in disparagement of research, but to urge attention to an urgently important matter, it would be a good boost to the cause of medicine if we could swap part of our scientific achievements for social equipment through which our science could get service—timely service—to those who need it.

PUBLIC HEALTH NURSING IN ITALY

By EDNA L. FOLEY, Superintendent, Chicago Visiting Nurse Association, Chicago, Ill.

WHEN the Tuberculosis Commission of the American Red Cross began its survey in Italy in 1918, it found sanatoriums, dispensaries, open air schools, and seaside heliotherapy stations; but no home visiting, no well established connection between the institution and the patient's family. Throughout northern and central Italy were various kinds of very well-built and, in many instances, well managed institutions—general and special hospitals; well baby conferences; schools for the blind, the deaf, and the crippled; with sometimes a little volunteer home visiting but no follow-up work of special cases of convalescents, and no home demonstration of food preparation for babies and small children. In fact, at an International Mutilati Congress held in Rome in October, 1919, at which the very excellent exhibits sent by France, England, and Italy made the entire absence of anything from America only more conspicuous, the physicians interested in the problems of the tuberculous soldiers discussed at length ways and means of keeping him happy and contented "away from his family." The visiting tuberculosis nurse has done a great deal to help us solve this problem in the United States but in Italy, before our courses, she was an unknown factor in the tuberculosis field.

Commission Organizes Work

The Commission arrived in Italy just before the influenza epidemic and physicians and nurses were loaned to small districts where nearly all the available physicians were in service and where nursing was unknown. Intelligent people were panic stricken, and the ignorant contadini terrified. In several towns, emergency hospitals were established and in others house to house visiting was done. Nursing, when whole families were stricken in their one-room homes, was almost impossible; for such homes were made to sleep in, the mattresses and pillows being stacked up in the day time. But this emergency visiting revealed the need of organized home work. Therefore the Commission decided to establish a training center for Italian public health nurses. This eventually took the form of four-month courses in Rome, Genoa, and Florence, scholarships enabling towns where anti-tuberculosis leagues were at work to send their candidates to the nearest course.

American Red Cross nurses were loaned to

The old Hospital del Ceppo in Pistoia, a small city one mile from Florence. The hospital was erected in the fourteenth century, and has served continuously since.

Vegetable women in a busy thoroughfare in Rome. Two men could hardly carry her load between them in this country, out no other means of cartage was provided.

A section of the facade of the old Foundling's Hospital in Florence, famous for the Della Robia babies. The blocked up space at the extreme end was originally the "Window of the Innocents" on which the foundlings were placed when their mothers wished to desert them. The hospital cares for other babies only when no foundling child requires bed space.

A group of villagers at Campo, Calabria, in southern Italy. The shacks are those erected immediately after the great earthquake of 1918 when Messina and Regio and other near-by towns in Sicily and Calabria were almost totally destroyed. Now the law permits only two-story buidings to be erected in this earthquake region.

New City Hall or Municipale in Campo, Calabria. The group of villagers is coming from the city store, where they may buy bread, macaroni, and corn meal on war tickets or tessare.

tuberculosis clinics and infant welfare conferences in three cities—Palermo, the hill-top town of Sezze in the Campagna, and the naval base of Spezzia. The field work that they established served as a practice district for the students.

As Italy has but three training schools and probably less than two hundred graduate nurses all told, Italian Red Cross nurses having had not less than two years of war work were encouraged to enroll as students. Each course was directed by a committee of prominent Italians. In Rome the president of the Committee of the Scuola Infermieri Visitatrice was also the chairman of the Section of Hygiene of the National Council of Italian Women, the Marchese Mariana Denti, a volunteer who had served with conspicuous fidelity throughout the entire war. In Genoa the school was established under the auspices of the provincial Lega Antitubercolare which gave the use of a well established clinic and its fine lecture room. In Florence the Committee was composed of prominent volunteers who were very much interested in securing better nursing care for their sick poor. In Rome and Florence the Committees were composed entirely of women, but the Genoa Committee was made up of men and women, the president being Professor Trambusti of the faculty of the University of Genoa.

Curriculum of Courses

Each course registered about fourteen students and the curriculum, as first outlined, copied in many details those of similar courses in America but when the schedules were given physicians for their approval, we found that some subjects which they considered essential and which we had taken for granted, had to be inserted. Consequently, lectures in anatomy and pathology took their turn with those in home demonstrations on infant feeding and investigating and reporting the need for relief to the proper local agencies. School nursing lectures were shared by professors of pediatrics and school inspectors because we found that the students had had nothing but adult work, and that only with soldiers. But in spite of the fact that the schedule seemed rather a mixture of training school and post-graduate material, the interest of the students, the sympathetic attitude of the physicians, and the more than average intelligence of the

This very modern laundry for a country district consists of two large tanks of cold water. The entire supply of clothes for many families is done simultaneously. The women like to gather at the wash place for a social afternoon or morning.

Italian girls made these seemingly ill adjusted studies fit very nicely into one another.

As the work was planned, the students spent every morning in the field making visits with the American nurses or visiting under their supervision. Afternoons were spent in the lecture room where daily conferences were held with the director of the course. A lecture was given by a physician and usually a second lecture was given by an American Red Cross nurse.

From the first the Americans interested in the course realized that their work in Italy was but temporary and that this work must be done by the Italians themselves if it were to be permanent. Therefore, nothing was done before a strong committee was established in each city and even then the Americans served simply in an advisory capacity. The responsibility for planning all the details of the courses but the lecture schedule itself was being left to the Committee. They found the rooms and financed securing them, furnished them, advertised the course, interviewed the candidates, and selected the students. As the first courses in Rome and Genoa drew near an end, the committees arranged with the physicians for the examinations, for the certificates, and for the assignment of the students to positions desiring them.

A Mutually Helpful Program

The courses went unusually well considering that they were an absolutely new venture and the American physicians and nurses who took part in establishing them learned a great deal about our Italian fellow-citizens. Most of the Americans spoke a little Italian and understood still more. Nevertheless, the difficulties of undertaking work of lasting educational value in a country where it was but imperfectly understood by very intelligent people were intensified on every side by this big handicap of not speaking a common language. To be sure, all educated Italians speak French and many of them speak English almost equally well; but educated Americans do not speak French and only one or two of the students in each group had any English, although probably 98 per cent of them spoke French easily. Telling everything through an interpreter is difficult enough at home in our own districts, but one has to lecture through an interpreter on a subject whose phraseology is of such recent creation in English that equivalent words are entirely lacking in Italian before one can appreciate the chief difficulty with which we met. It was easy enough to find a person who spoke and understood English fairly well but to pass one's ideas over to this interpreter so that she really gave the correct thought rather than her interpretation of your thought to the class, required a very extensive English vocabulary on the part of the American Red Cross instructor and an equally extensive Italian vocabulary on the part of her interpreter.

The more one uses interpreters, the more one appreciates that only the rare individual makes a successful go-between. For instance, a very busy, interested and earnest superintendent of schools, whose teachers were doing a piece of work as significant in its sociological as in its educational aspect, was asked by an interpreter who spoke very good French if he would lecture to our students. He seemed a little bit surprised but said that he would. A few days later we dis-

An Italian child in this group of children is walking off with a bundle on her head which is carried as unconcernedly as if it were a new spring hat.

covered that the interpreter had asked him if he would collect all of his school teachers and let the American director of the first course lecture to them. How this Italian so misconstrued perfectly good French, which we thought he spoke easily, is a mystery still unsolved; but that one incident made us go very slowly whenever we were making the simplest request through a new interpreter.

Needs of Special Communities

At the expiration of the course in Genoa, five students were put into the public schools under the supervision of Professor Ragazzi, who holds a position in the Department of Hygiene analagous to that of our chief medical school inspector, and others were assigned to various dispensaries and conferences asking for them. We

It is not an uncommon sight in Italy to see flocks of goats being driven through the streets. The housewife hears the bells in the distance, takes her bottle to the door, and the goatherd stops the flock and then and there milks into the bottle the desired amount.

found that there was a very distinct need for tuberculosis home work, for work with well babies and with little children. In and about Rome we found a great deal of trachoma and malaria but, to our very great amazement, we discovered almost no illness in the homes except in the more isolated districts where there were no hospital facilities. In Palermo there are not nearly enough beds to meet the needs of the population; this was the only city of any size where we found sick people in bed at home, or ill enough to have been in bed.

In the small country towns we occasionally found an advanced case of tuberculosis or a confinement case suffering with complications, but in the larger cities where there are many civil hospitals, whose service is free to the poor, we did not find a single bedridden case. We were amazed at the number of dressings that reported daily to dispensaries, even when the patients made the trip with a great deal of difficulty. Italian physicians and volunteer workers assured us that they felt there must be a very great need for visiting nursing to the sick but our investigation, which extended over eight or nine months, did not bear out their statements. We did find many people who seemed to us ill enough to have been in bed had their homes been adapted to this sort of treatment, and we were told that the long waiting list which practically every hospital had would be considerably reduced if patients were dismissed earlier, but that the lack of any kind of home service delayed the discharge of convalescents.

However true this may be, we found practically no illness in the homes nor could we understand why the average Italian in America has such a deep-seated prejudice against hospitals when in his own country he seems to go to them readily enough. Undoubtedly this is because our hospitals use English only and are reasonably well ventilated. The Italian lives so constantly in the fresh air during the day that he rather strenuously objects to fresh air at night, and perhaps our hospitals have too much of it.

The Red Cross was able to assist the local committees to complete the first courses in Rome and Genoa and to see second courses in both these cities and a first course in Florence well on their way before the nurses were all withdrawn January 1. Through friends of Dr. William Charles White, the director of the Commission, scholarships have been secured on which several Italian students are to come to America for further training and study. It was gratifying to the Red Cross workers who had the privilege of sharing in these courses, to feel that the comparatively young United States of America has something to give a country whose civilization is as old and as well established as is that of Italy, and the workers very much hope that these modest beginnings may help to secure infinitely better care for the many patients in Italy whose needs, up to the present, have frequently gone unrecognized.

THE EUROPEAN HEALTH SITUATION

The recent service of Surgeon General Cumming on several international boards gives especial significance to his expressed opinion that typhus in Asiatic countries is still unchecked and only the strictest measures of control will serve to prevent its invasion on a wide scale in Europe. Living conditions should prevent the menace of typhus in America. He expressed the belief that the health work of all nations should be strengthened and coordinated to improve the reporting of diseases and the maintenance of quarantine between nations.

A meeting is to be held in London on April 12 to which officials and representatives of the health departments of various nations have been invited, at which time it is believed a permanent organization will be formed. The United States will send a representative to this conference, Dr. Cumming said.

THE CHICAGO INFANT WALFARE SOCIETY

By SARAH B. PLACE, Superintendent, Chicago, Ill.

Annual report of the Superintendent of the Chicago Infant Welfare Society, February, 1920.

This Society has for its objective, the reduction of the infant death rate and the improvement of the health of the coming generation by keeping the baby well both before its birth by caring for its mother, and after its birth by teaching the mother how to feed and care for the infant. During this past year what progress have we made in approaching our goal?

Child Welfare mother and baby.

Progress this year has been along very definite lines. We have reduced again our infant mortality rate, and we have developed new work with the child to six years of age. To those of us who are very near the work and to whom its development is very dear the demonstration is made time after time that our greater value to this community lies in emphasizing the vital need of giving mothers early care and of keeping the child well after its birth.

Dr. Helmholz will report on how we have succeeded with the medical side of the problem. The entire story is not told in terms of mortality rates and well babies, however. Not only are we saving twenty-three more babies per thousand than in the first year of our work, but our influence is being felt in the home in a great variety of ways through safeguarding the welfare and comfort of the family group. Some time ago a mother who had much to learn regarding the feeding care of her baby, and who had repeatedly turned to our station for help, came early one morning with a bundle of heavy material asking the nurse to cut out a coat for the child. Fortunately for us, this nurse was particularly skillful along this line, and a few minutes later a very light hearted mother betook herself home to complete the garment.

The Work Is Educational

Ours is an educational piece of work, and we do teach mothers how to care for their own. This must not be construed to mean that nurses are content to reiterate and emphasize the doctor's instructions and watch the mother carry them out. It does mean that the nurse follows the instructions of the doctor and does such other things about the home as are advisable. It is a message of deeds as well as words which we carry into the homes.

Our prenatal work has been possible through the splendid cooperation we have had with Rush Medical College, and the Out-Patient Department of the Presbyterian Hospital. We have twice as many mothers coming to the Milton prenatal clinic this year as last.

It is no longer necessary to argue the need of such work. It remains now but to carry out plans making it possible to swing the very big program ahead of us, and we hope 1920 will see us well launched on our program for pre-natal and post-natal care for every child in our twenty-three stations.

Early in February, we will add a complete station—that is, a station with a pre-natal clinic, our regular mothers' conferences, and a nutrition clinic—which will be supported through the interest of the Child Welfare Committee of the Woman's City Club and will be located in territory adjacent to a long established district northwest.

A plan for reaching more district babies as soon after birth as possible has been in operation several years. Through the activities of the birth registration nurse follow up calls are made in our district homes in which we have a birth registration report through the city hall.

Where is my nurse?

Every year we are helping an increasingly large number of mothers to solve the problems of early infancy. During the month of December there were registered in the city hall 1,037 births which were within the boundaries of some one of our twenty-three districts.

When births are not registered, we often encounter dire results. A striking example came to our attention within the past ten days when a district grandmother came to ask the nurse to come and see the eyes of a new born infant. Going immediately, the nurse found a condition which necessitated prompt hospital care for the child. The midwife had not reported the birth, had not used the prophylactic treatment provided gratis by the State Health Department, and had not reported to the local au-

Who started this bathing business, anyway?

thorities the condition of the child's eyes—all of which subjects her only to prosecution by the State Board of Health—but the child to a life of impaired vision.

Extent of the Service

This year we have cared for 257 babies through the Home and Aid Society, making 2,352 calls. With the establishment of the work with the child to six years of age, we hope the time will soon come when the Home and Aid Society can have more than one nurse do this important work.

In inaugurating the work with the child to six years, it has seemed most necessary to add a staff of dietitians who are doing for the child of pre-school age what the doctor has been doing for the baby under two, directing the feeding. Splendidly enthusiastic work has been done by these women and we are confident that the recent decision of the county agent to supply milk to children under four years instead of the previous two year age limit is due, in a great measure, to the efforts of our dietitians. The county agent has in a number of instances changed county rations to more nearly suit the needs of an individual family when his attention has been called to it by our dietitians. We very much appreciate this splendid cooperation, as it does very materially help us in solving an otherwise hopeless problem.

Our stations have had this year a total conference attendance of 18,525. During the year, the nurses have made 80,264 calls, having cared for 8,793 babies. Not only is the educational work carried on in our own community, but the fact that we have sent ten of our nurses into other public health fields, indicates that we have contributed materially to the national campaign for more adequate child welfare work.

The Chicago School of Civics and Philanthropy gives a course throughout the year in public health nursing. During 1919, Infant Welfare gave a half day's intensive instruction and additional days of field work to 135 student nurses in connection with this school.

Such work is possible only through the splendid cooperation of all interested, cooperation being interpreted to mean the working together for one purpose and in its broadest application covers all interchanges of courtesies and assistance between workers. The work this Society does could not be accomplished without the conscientious effort put forth by doctors and nurses, whose work in turn would be quite fruitless were it not for the thousands of mothers who are eager for more knowledge, more light; and the entire story might be left untold were it not for our some seven thousand friends whose share in the cooperation is the generous giving of themselves.

THE SCARCITY OF NURSES

A petition has been made to the Massachusetts State Board of Health which proposes to relieve the scarcity of nurses by the creation of a class of nurses to have the title of "licensed attendant," this right to be conferred on persons of at least eighteen years of age, and nine months' training as attendants under proper professional conditions.

Dr. Walter P. Bowers, secretary of the State Board of Registration of Nurses, expressed himself in the discussion of this measure as in favor of grading nurses into Classes A, B, and C. The bill is supported by Dr. M. E Champion of the State Board of Health, and by the Massachusetts State Nurses Association.

There are about nine thousand nurses in Massachusetts and the requirements of training need to be modified so as to shorten the period of preparation for the $18 to $25 a week class. It is believed the petition presented would draw nurses recruits from the ranks of other professions.

The measure is opposed by Dr. E. H. Cohoon and Dr. George O. Clark on the ground that it is bad legislation and would reduce the facilities of the small hospitals to get the class of nurses they want.

MENTAL RETARDATION AMONG CHILDREN

In some observations on mental defectiveness and mental retardation among children published in *Public Health Reports* of April, 1919, Walter S. Treadman makes a plea for the recognition of borderline cases. Another method is one of gradations, and serious mistakes are made by classifying as feeble-minded, children whose mental development has merely been retarded. Feeble-minded children lack equilibrium and proper balance and are usually presumably insane in showing either intellectual or moral degradation, or a combination of the two.

The grading of children by the Binet-Simon scale gives, for educational purposes, a comparatively quick insight into the mental capacity of children; but as applied to adolescent cases, the mental equipment being more complex, is less accurately measured by an arbitrary schedule.

In attempting to decide between retarded mental development and feeble-mindedness, the question of neuropathic predisposition is sometimes given undue importance. In many cases faulty habits of training are

responsible. Environment also plays a part. Limited educational opportunities also play a part in the failure to score a high mark or credit by formal psychological tests.

Inquiry into the total of mental makeup of the child should be made and considerable training methods adopted to develop the desirable traits and restrain the undesirable ones. In these borderline cases, mental hygiene takes prominent rank in the role of preventive medicine.

CARE FOR MALNOURISHED CHILDREN

The problem of the malnourished child is beginning to receive the attention it deserves, and a solution is being sought by the numerous agencies interested in health

An occasion for congratulation. This youngster knows he is moving up the line of proper weight for height. (International Film Service.)

work. Dr. William R. P. Emerson and his assistant, Miss Mabel Skilton, who have made remarkable progress in this line in Boston, have been called to other cities to demonstrate their methods and line up various organizations for the spreading of information on the subject.

In one section in Boston out of 500 children examined there were only fifty-one whose weight was normal in relation to height; only thirty-three were over-weight, and only 100 showed no defects. Practically 40 per cent of the defectives had rickets. The other more serious defects were bad teeth, enlarged tonsils, pediculosis, and coryza.

Making a record of a malnutrition case at the Dante School, Boston, the examination being made by Miss Mabel Skilton. (International Film Service.)

Out of 416 children examined who were underweight, 235 were foreigners, the largest percentage of these being Irish. The next in order were Russian, Italian, and English.

The work as carried on in Boston consists first in home visits by public health nurses who make the necessary explanations in order to get the children into the classes, and also get facts about the homes which are helpful in the after treatment. Once the children are enrolled in the classes, competition is of great assistance in securing the necessary cooperation.

The children from the clinics are referred to the various agencies already existing which do work along this line, and these agencies report to the Child Welfare Committee once each month, so that the Committee is able to keep a record of each child until such time as his condition warrants discontinuance.

Examinations made of children of pre-school age indicate that there is great need of health supervision for children under six years of age.

FREE CLINICS FOR RURAL DISTRICTS

The Interchurch World Movement has adopted as a part of its health program the establishment of free clinics in rural communities. These clinics are to be held in remote sections by prominent physicians and surgeons from medical and hospital centers. They are to include treatment as well as diagnosis.

The organization sets the problem of sickness thus: The position of the sick, especially if they be also poor, is desperate enough in cities. New York City has forty-five non-municipal hospitals; they care for one million patients annually, but are always crowded and compelled to turn away great numbers of applicants because of lack of room. Five thousand sick persons are said to be denied admission every day to hospitals under the auspices of Protestant churches in the United States because of inadequate accommodations. The Interchurch program aims to meet and supply this great need and to meet also the country's need.

Knowledge of disease is lacking, and the facilities for its treatment not at hand. The plan for the rural clinics provides that they be held two or three times each year in the selected communities and that they last one week. Persons with organic diseases and congenital troubles will be encouraged to attend, and especial effort will be made to bring children to these clinics in the hope of stamping out inherited disease before it has had opportunity to develop, or to be transmitted. Free dispensaries are also provided for in the plan.

MATERNITY CENTERS IN NEW YORK

Thirteen foreign countries have a lower average rate of infant mortality than the United States, according to a report of the work of the maternity centers in New York. The Maternity Center Association, New York, was founded less than two years ago. These centers are intended to be a clearing house for maternity work. The need of extending the work is shown by the fact that there are still 75,000 expectant mothers in New York without medical or nursing oversight.

The estimated result of the work in maternity centers has been a reduction of 75 per cent in the death of the mothers and 40 per cent in the deaths of babies in premature deaths.

DEADLY POISON IN CANNED GOODS

The death of several persons from eating ripe olives has caused physicians, health officers, and bacteriologists to give close attention to the prevention of such poisoning. Dr. Howard S. Breed, bacteriologist, in a recent statement declared regarding botulism:

"Botulism is the name of the poisoning caused by the growth of a comparatively rare bacterium, Bacillus botulinus. It was originally described in 1899 by von Ermengen as found in spoiled ham. This outbreak in Belgium and other early cases were associated with spoiled meats. Recent American cases have come from spoiled canned goods. Up to January 10, 1920, there were forty recognized outbreaks in the United States, which affected 150 persons, with ninety-three deaths.

"These outbreaks were associated with spoiled canned string beans, asparagus, beans and ripe olives, all of which were eaten uncooked. Most of the trouble has come from home canned goods until during the past six months, when there have occurred outbreaks from eating ripe olives at Detroit, New York, Canton, O., and Memphis. This has caused the Bureau of Chemistry and the commercial canners to withdraw so far as humanly possible all suspicious goods.

"In all of the ripe olive cases the persons eating them admitted that they knew the olives were spoiled. Those who ate them at Canton said they smelled like limberger, bit the tongue, were soft, not fit to eat, and stuck to the tongue.

"The deadliness of the poison produced by the bacterium in decomposing the olives is shown by the fact that one person died who ate only half an olive. Death is caused by the poison bacteria, as Bacillus botulinus in the olives, not by a disease caused to grow in the human body.

"Danger may be avoided by discarding all canned goods showing any evidence of spoiling. All danger is avoided by not eating any canned vegetables until after they are cooked. Cooking destroys the poison. Prudent persons will also avoid using home canned vegetables for salads, even though they appear good, as Bacillus botulinus has been found in some canned goods where there was no evidence of spoilage. Commercial canned vegetables are safer than home canned as they are sterilized at higher temperatures. Unspoiled canned goods are always safe to use if they are cooked after opening."

NATIONAL PHYSICAL EDUCATION

An interesting discussion of the position of the medical profession in relation to national physical education is contributed by R. Digby Bell, M.R.C.S., L.R.C.P. Lond., in *The Lancet*, January 31, 1920. Dr. Bell states that the study of physical education has concerned him since 1906 and that his connection since that date has led him to regard physical recreation as a necessity to counteract the possible onset of a depression due to the incessant nervous strain and ghastly monotony of some forms of the service. He submits a schematic arrangement of the different phases of physical education which he divides into three main headings: (1) activity developed by physical training, (2) energy developed by recreational training, and (3) character developed by morale training.

Anatomy and physiology come prominently under preventive measures. Constructive measures involve the application of bodily exercises to the young to insure as perfect a body as it is possible to require. Continuity of physical education is provided by a series of activity measures simple in character requiring two minutes to do which are compiled to provide full and free movement of the body in an interesting and attractive form. He speaks of the assistance of corrective physical training in the department of orthopedics. Research in corrective orthopedic work is provided for in his scheme. Unscientific exercises can be defective, both anatomically and physiologically.

He regards it as utterly scandalous that the British should be ranked as a C3 race as regards physical fitness and considers athletic competitive sports in which all the people participate the only possible correction. All efforts have failed to provide a national program and he calls upon the medical profession to awaken the country to the necessity of physical education as a measure of preventive medicine.

CONNECTICUT TUBERCULOSIS COMMISSION REPORT

Marked progress is shown in the tuberculosis campaign in Connecticut during period from October 1, 1916, to Sept. 30, 1918, covered by their last report. Despite the paralyzing effects of war and pestilence, there has been a sympathetic interest on the part of the public scarcely duplicated in any other part of the country. The special need is urged of better supervision by the state for its children crippled with bone and glandular tuberculosis. The Commission urges the concentration of effort where there is hope of cure, and believes that general hospitals of the state should be compelled to provide wards for the care of emergency and dying cases of tuberculosis.

An interesting feature in the study of tuberculosis is that it kills more city men and more country children. It is pointed out, however, that the controlling factor is density of population and that the average density of population in some "rural" towns is higher than the average density of population in many urban towns.

There is here as elsewhere a shortage of nurses, and the need of a thorough development of a tuberculosis dispensary system. The report points out the fact that the tuberculosis situation might be met by institutional care. The real hope of correction is in educational measures.

WAR'S EFFECT ON FRENCH CHILDREN

The effect of the war on the children of France is shown in a recent report submitted by the American Red Cross headquarters at Lille. The figures are furnished by the Municipal Bureau of Hygiene.

The city had a pre-war population of 200,000. The birth rate has shrunk from nearly 4,900 in 1913 to only 600 in the past year. The figures by years follow: 1913, 4,885 births; 1914, 4,540 births; 1915, 2,155 births; 1916, 640 births; 1917, 600 births; 1918, 600 births.

The death rates according to ages are not known, but since the armistice a survey has been made in all public and private schools with a view to obtaining appropriate food for all children whose development has been retarded, and to place all those who show signs of tuberculosis in the care of institutions and welfare organizations. Of 18,000 children in school at Lille at the time of the armistice, more than 6,000 had to be sent to hospitals or convalescent centers.

This survey indicated that 60 per cent of the school population showed signs of arrested development, while about 40 per cent gave evidence of ganglionary or pulmonary tuberculosis. In one typical school, out of 210 examined, only one was in normal health.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

THE PHYSICAL BASIS OF HEREDITY. By Thomas Hunt Morgan, professor of experimental zoölogy in Columbia University.[1]

This volume comprises an authoritative exposition of the mechanism of heredity by one who has done much to expand the basic principles of Mendel to their present status. Throughout, a close correlation is preserved between the analysis of actual breeding data on the one hand, and the cytological evidence for an adequate chromosomal mechanism on the other; this treatment constitutes the most novel and valuable feature of the work, and by it the pedagogy of genetics marks a distinct advance.

Those who have not followed the rapid progress of genetic facts and concepts will be struck by the amount of water that has gone through the mill since the "early," yet in reality comparatively recent, days of "Mendelism." The important principles of linkage, including sex-linkage, crossing-over, linear order of the genes, interference, and the limitation of the linkage groups are largely the result of prodigious labors by the author and his associates. As might be surmised, their analyses and inferences far outstrip the correlative cytological evidence, but, even so, recent chromosomal studies tend to confirm dramatically many of their conclusions and predictions. The bulk of evidence is drawn from data on the fly, Drosophila. This is to be expected, not only because the author's experience has been largely confined to this form, but also since the analysis is here quantitatively most complete.

One misses the customary setting of historical and evolutionary principles, as well as such topics as statistical methods, the relation of germ plasm and soma, human heredity and eugenics; these subjects, and a general treatment of genetics based largely on mammalian data, are to be found in a recent book of essentially similar scope by Professor Castle. These two American texts, which in many respects supplement each other, furnish the most satisfactory exposition of genetics existent.

As a text for undergraduate use Professor Morgan's book will not be found "easy reading"; this need not reflect on the lucidity of treatment, which shows a master's skill, but rather the difficulty is inherent in the subject matter; yet anyone who earnestly reads and ponders will be amply repaid.

THE AFTER-TREATMENT OF SURGICAL PATIENTS. By Willard Bartlett, A.M., M.D., F.A.C.S., and Collaborators.[2]

There is undoubtedly a definite demand for a good book on after-treatment. Bartlett and his collaborators attempt to fill this demand. In two volumes, the postoperative period, the sequelae, and complications which are apt to arise, are dealt with in detail. There are many interesting and practical points. The method, for example, by which the interest in a patient using the Blow-bottle during empyema is stimulated by attaching a manometer is ingenious and extremely useful. The work is well illustrated. The book, however, contains more operative technic than is essential. A book on after-treatment, moreover, should presuppose a broader knowledge of surgery and should lay more stress on the after-treatment *per se*, especially of the more common operations. Bartlett's work contains much that is good, much that might well be omitted, and lacks some things which might well be added.

MODERN SURGERY. General and Operative. By John Chalmer De Costa, M.D., LL.D., F.A.C.S., Samuel D. Gross, professor of surgery, Jefferson Medical College, Philadelphia; surgeon to the Jefferson Medical College Hospital, consulting surgeon to Philadelphia General Hospital, St. Joseph's Hospital, and Misercordia Hospital, Philadelphia, etc.[3]

In one volume De Costa has condensed the essentials of surgery. His book contains the fundamental principles and a surprising number of details. There is an urgent need for just such a book. In this day when volumes are being written about a small group of organs or some single viscus, it is difficult often for the surgeon himself to "read up" a case. For the general practitioner or the student it is often almost impossible. They are apt to feel like the man in the old saying who cound not see the forest because of the many trees. De Costa's Surgery continues to be, as in the past, a good reliable guide through this intricate surgical forest. The last edition has been revised to keep abreast of the modern advances. The lessons the war has taught have been incorporated.

De Costa's "Modern Surgery" is an excellent book for the student and the teacher, for the surgeon and the internist, for the specialist, and for the general practitioner.

Would that the reviewer's task were always as pleasant and as profitable and his recommendation as easily and sincerely given.

SAFETY FUNDAMENTALS. Lectures by the Safety Institute of America (Maintaining the American Museum of Safety) on alternate Saturday mornings, from February 1 to June 7, 1919, for the benefit of factory inspectors employed by the City of New York, the states of New York and New Jersey, and insurance companies operating in and near New York City.[4]

The foreword of this book calls attention to the fact that inspection is more than fault finding and constructive criticism implies special training for inspectors. The book itself grew from material drawn from lectures given in free training courses in inspection.

In the opening chapter Dr. F. C. Smith, of the United

1. J. B. Lippincott Company, Philadelphia.
2. C. V. Mosby Company, St. Louis, 1920
3. W. B. Saunders Company, Philadelphia, 1919.
4. Safety Institute of America, New York, 1920.

States Public Health Service, treats of the "Body Which Gets Hurt" under such topics as the relation of health to labor stability, the relation of health to accident frequency, the increasing mortality at middle age, the importance of health breathing apparatus, the digestive tract, and oral hygiene. It constitutes a treatise which embodies a practical statement of normal function and how it may be maintained, and gives incidental warning of the deterioration of function from fatigue or lack of hygienic care.

Dr. Loyal A. Shoudy takes as his topic the care of the "human machine." What constitutes an injury is considered and the fundamental principles of first aid work expanded.

The safety fundamentals embodied in suitable clothing for workers are handled in chapters by R. M. Little and Adelaide Wood Guthrie. "Safe Heads and Good Eyes" and the "Cooperation Necessary to Eliminate Eye Accidents" are contributed by Walter G. King, of the Julius King Optical Co.

The subject of safety is well rounded out in succeeding discussion of the guarding and arrangement of machinery. Illumination, and special hazards incidental to certain natural forces. Safety organization and shop organization complete the series.

The book is a compendium of rational practice and a statement of the raison d'être of the safety movement for the use of managers, inspectors, or the men themselves. Its value is further increased by a full bibliography.

THE WOMAN OF FORTY. By Edith B. Lowry, M.D., author of "Herself," etc.[5]

Two facts are quite evident. Dr. Edith B. Lowry in numerous preceding contributions has proved her rare ability in elucidating to the lay reader many of the intricate aspects of the sex problem. There exists a definite need for this type of book. In this new volume the versatile author discusses the particular problems of the woman of forty. They pertain to health, appearance, clothes, occupation, happiness, and satisfaction; and they all are dealt with thoroughly correctly, intelligently, and even cleverly. This is a pleasant book to read—for the physician to get a clearer conception of the woman's point of view, and for the woman of forty to learn what a physician has to say about her.

FATIGUE STUDY. The Elimination of Humanity's Greatest Unnecessary Waste. A First Step in Motion Study. By Frank B. Gilbreth. Member of American Society of Mechanical Engineers; member Franklin Institute; past vice-president Society for the Promotion of Engineering and Education; honorary member Society for the Promotion of Occupational Therapy; and Lillian M. Gilbreth, Ph.D.[6]

The elimination of unnecessary fatigue involves a scientific study of both work and worker. It would entail the saving of $300,000,000 annually in producing and earning capacity and would incidentally remove other and unnecessary wastes.

The fatigue study presented by Mr. Butterworth was undertaken with a view (1) to determine accurately what fatigue results from doing various types of work; (2) to eliminate all unnecessary fatigue; (3) to reduce the necessary fatigue to the lowest amount possible; (4) to provide all possible means for overcoming fatigue; (5) and to put the facts obtained from the study into such form that every worker can use them for himself and get more out of life.

The investigation emphasizes the importance of the human element in work, classifies fatigue, outlines methods for the elimination of unnecessary fatigue and for the provision of rest periods, all of which results in improvements in relationships. It becomes evident that it is unintelligent to work at top speed part of the day and be in a state of exhaustion the rest of the time. The management is relieved from the imputation of trying to overwork the men. Better output ensues, and the spirit of cooperation grows.

Factors of fatigue elimination are discussed under conditions of illumination and ventilation, fire and safety protection. The improvement of general working conditions enters into the problem. Changes are made looking toward immediate betterment, adjustments from time to time developing into standard practices. The test of efficiency is in the improved health of the worker, in his prolonged activity, his posture, and in his conduct.

The modern trend in this movement is exemplified in the demonstration by Dr. Southard of the place of mental hygiene in industrial development and of Frederick S. Lee of the place of the physiologist as an investigator in this field. It is in the highest sense a constructive problem.

CHILD WELFARE IN KENTUCKY. An Inquiry by the National Child Labor Committee for the Kentucky Child Labor Association and the State Board of Health. Under the direction of Edward N. Clopper, Ph.D.[7]

Kentucky has recognized the importance of protecting its children from premature employment and has enacted a labor law with standards higher than those of neighboring states, says Mrs. Loraine T. Bush, in Child Welfare in Kentucky. But are the children deriving from it all the benefit the state intends they should?

Indifference and lack of knowledge of the child labor law on the part of employers in certain towns are amazing. Abuse in the matter of permits largely defeats the child labor law. Except in Louisville, documentary evidence of age is rarely filed. Physicians certificates do not record, as required by law, the height and weight of the children receiving work permits.

A serious omission in the interest of the children is the exemption under the Kentucky law of children employed in agriculture and domestic service, as 82 per cent of the child laborers are reported in agricultural pursuits. The only restriction to child labor in agriculture is in the compulsory school laws, and these are very contradictory and generally disregarded in rural communities.

Many instances are cited of children no older than eight or nine years who work side by side with adults and whose attendance at school is cut down to less than one-third, with the natural consequence of general retardation among farm children.

The recommendations urge the adoption in Kentucky of the standards of the Children's Bureau with Periodical medical examination of all working children under eighteen years of age. Provision for inspection and enforcement under labor laws is essential for effective work.

NURSING IN DISEASES OF CHILDREN. By Carl G. Leo-Wolf, M.D., chief of the clinic for sick babies and children for the health department of the City of Buffalo, N. Y.; instructor in pediatrics, University of Buffalo, Medical Department; author of "The Child in Health and Illness."[8]

After a careful reading of Dr. Leo-Wolf's little volume on nursing in diseases of children, one feels that it might

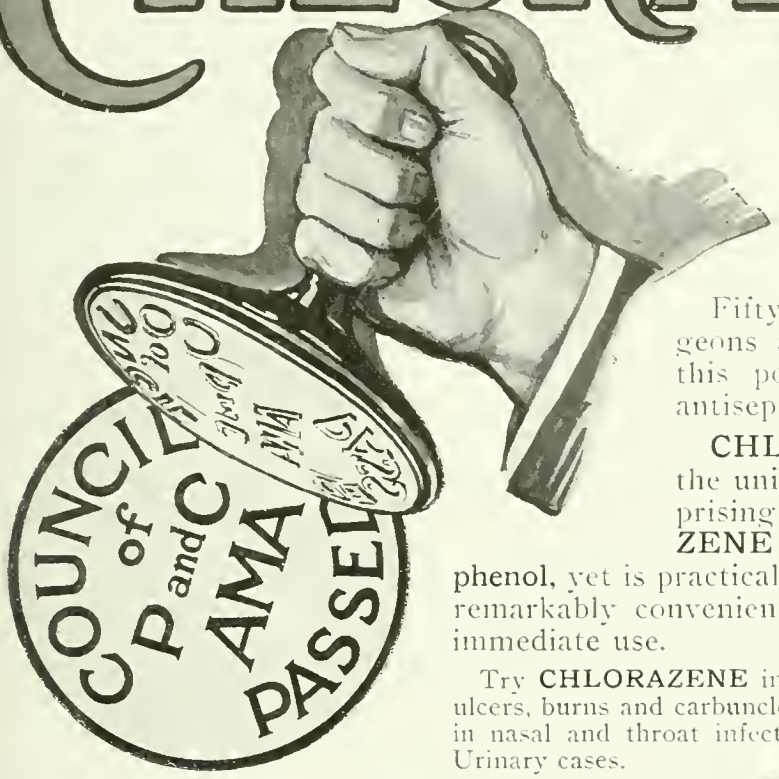
CHLORAZENE



A Real Antiseptic

Developed by Dr. Dakin as an Improvement over the hypochlorite solutions used by Carrel.

Fifty thousand physicians and surgeons are now using, with satisfaction, this popular, powerful, Council passed antiseptic.

CHLORAZENE is rapidly becoming the universal antiseptic. This is not surprising when you know that CHLORAZENE is fifty times more powerful than phenol, yet is practically non-toxic. It is safe, stable and remarkably convenient, in tablet and powder form, for immediate use.

Try CHLORAZENE in all pus infections, in surgery, wounds, ulcers, burns and carbuncles, in fact wherever there is pus. Use it in nasal and throat infections, as a douche and in your Genito Urinary cases.

CHLORAZENE is supplied in Tablets and Powder form. Also as CHLORAZENE SURGICAL CREAM, CHLORAZENE SURGICAL DUSTING POWDER, CHLORAZENE GAUZE and AROMATIC CHLORAZENE POWDER for oral and nasal use.

Send for interesting booklet on the Dakin Antiseptics, Chlorazene and Diehloramine-T

Urge your druggist to stock CHLORAZENE for your convenience in prescribing. In the meantime your orders will be filled directly from our home office or convenient branch points, as listed below.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRITPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 340)

well become a very constant companion for the nurse. It would certainly be of distinct value to many physicians as well. The book is a simple, straightforward conversation between a man and his associate workers, who are also his friends; a man who, while he would demand the utmost obedience from his nurses, would be inclined always to give them full credit for the good results for which they have been responsible.

The next thing which strikes one is the very great care that the author has taken to explain the "little things" which are so seldom mentioned in the textbooks. These are the details which the nurse often fails to have at her fingers' ends but which she often hesitates to ask of the physician because he sometimes scoffs more or less at the things which she wishes to discuss as important. It is the big man who recognizes the value of the so-called nagging details and, also, that especially with women, both nurses and mothers, there is often a real ability to note detail of all kinds. Many training schools cannot give the nurse sufficient individual training to prepare her for all the exigencies of private nursing, and too often she blunders because no one has impressed the importance of simple things upon her. This Dr. Leo-Wolf does to a very noticeable degree, and his frequent admonition to the nurse "to put yourself in the patient's position" is certainly very pertinent. If all doctors and nurses did that more frequently, how different would be the history of the patient's experience.

The first two chapters of the book, the introduction and that headed "Physiology and General Considerations," give a good working basis, but with no superfluities. The third chapter, that on clothing, is very different from the matter before and after, and is the poorest one in the book. It is too short, too one-sided in opinion, and would not be practical generally, because it advocates unqualifiedly for the layette a number of things which many good pediatrists do not use. The chapter on infant feeding is a joy because it sets forth a positive plan, at the same time warning the nurse not to feed babies herself unless absolutely necessary, but still places in her hands a rational procedure in case she should be left, in an emergency, alone. The chapter on the examination of children is full of practical hints for both doctor and nurse and, again, there is much of practical value in the discussion of the nursing of sick children and infections.

Of course, the nurse is always the victim of the fact that no two doctors take care of their children in at all the same way, and one would naturally differ on occasion with Dr. Leo-Wolf; but there are very few textbooks where there is expressed as fair an opinion of the other man's point of view. Furthermore, the book is a relief because it does not have the mixture of physiology and anatomy, nursing and *materia medica* that one finds jumbled together in so many of the nursing textbooks.

A TEXTBOOK OF PHYSIOLOGICAL CHEMISTRY. By Olof Hammarsten, emeritus professor of medical and physiological chemistry in the University of Upsala; with the collaboration of S. G. Hedin, professor of medical and physiological chemistry in the University of Upsala. Authorized translation from the author's enlarged and revised eighth German edition by John A. Mandel, Sc.D., professor of chemistry in the New York University and Bellevue Hospital Medical College.[3]

Hammarsten's "*Physiological Chemistry*" remains to this day the best and most concise encyclopedia on the

Measuring cap which double-seals the cork.

SOFOS

SOFOS is a product of the research laboratories of the General Chemical Company—one of the world's leading scientific organizations—a strictly American institution.

The Reason for "SOFOS"

—A New Preparation

The reason why sodium phosphate is not used more extensively lies not in its inability to exert the physiological action ascribed to it, but the failure to employ the ideal and therefore most active form.

The "reason why" of sodium phosphate success will be found in

SOFOS

Because SOFOS, a preparation of monosodium phosphate and sodium bicarbonate, has the same phosphate value as 1¾ times U. S. P. sodii phosphate.

Because SOFOS contains no citric or tartaric acid and after effervescence in water yields di-sodium phosphate *only*.

Because SOFOS is efficiently laxative or purgative according to dosage, without griping or "nagging."

Because SOFOS is pleasant and agreeable to the taste, adapted for children, old people, debilitated or delicate persons.

Because SOFOS is intended for professional use, and will be ethically introduced to the medical profession.

Because a test of the performance of SOFOS will fulfill and justify the promise of SOFOS.

SOFOS has been accepted by the Council on Pharmacy and Chemistry of the A. M. A. for inclusion in New and Non-official Remedies.

Ask your pharmacist for SOFOS. If he hasn't any, notify us.

BOOKS OF THE MONTH

(Continued from page 22)

subject. When one is in need of a comprehensive review of any subject in physiological chemistry, he can find what he wants in a few minutes in Hammarsten. Not only does one find good subject matter, but also excellent reference on the subject.

With all this, Hammarsten is not a textbook, but rather a reference book. Although some of the best physiological chemists in this country and abroad were brought up on Hammersten, the book does not appeal to the average student, for the average student does not want to read short sentences containing dry statements, without any comment on the part of the author—something which is characteristic of Hammarsten. If one would dare suggest an improvement upon an old standard like Hammarsten, it would be this: to add at the end of each chapter a short summary of the subject matter with a decisive opinion of the author or the translator.

DIABETES. Its Causation and Treatment (with special reference to India). By Ernest E. Waters, M.D., (Edin.), M.R.C.P. (Lond.), Lieutenant Colonel, Indian Medical Service, Civil Surgeon, Howrah, Bengal.[1]

The author states that he is considering diabetes from the Indian standpoint and the position of the practitioner in the East. However, he devotes the major portion of the book to reviewing the evidence offered by a few investigators relative to the physiology and pathology of the disease. No new experimental data are reported. Some statistics are given which are very striking when it is recalled that the natives of India are vegetarians. For example, in 1914 of a third of a million people there were only twenty-three admissions and two deaths from diabetes. The most important chapter is that in which dietaries including Indian dishes are given, with the value of the whole diet calculated. The book may be of some slight value to practitioners in India but not elsewhere. There are many typographical errors throughout the text.

DISEASES OF THE STOMACH, INTESTINES AND PANCREAS. By Robert Coleman Kemp, M.D., professor of gastro-intestinal diseases at the Fordham University Medical School, gastro-enterologist at the Fordham University Clinic, etc.[2]

This is one of those rarer books which is almost indispensable to the surgeon and to the internist, and at the same time of special value to the general practitioner. Its principal virtues are thoroughness coupled with conciseness, virtues which are not possessed by every medical work. Its consciseness makes it very readable. One does not have to wade through a mass of words to find the facts.

Anatomy and physiology are covered very briefly, but there are several very thorough chapters on physical and chemical examination. A separate chapter is devoted to x-ray findings. The chapter on diet is very complete. Considerable space is devoted to physical methods of treatment, including electricity.

In the consideration of the various diseases and abnormalities, a great deal of attention is paid to the differential diagnosis. In this respect acute abdominal lesions are most thoroughly discussed.

The treatment is stated fully, yet concisely, all approved methods being mentioned. In those lesions where only surgical treatment is of value, the *modus operandi* is briefly described.

What is the Money Value of Good Sound Sleep
Does anyone ever get "too much" Sleep
You Need Sleep even More than you need Food
Can Lost Sleep be "Made Up"
Why do People Wake up only Half Rested
How Often do you get Really Refreshing Sleep
Can You Do More Work by Neglecting Sleep
IONS BEDS
Built for Sleep

The medical profession is not alone in its efforts to encourage better habits of sleep

FROM time to time in this space, attention has been directed to Simmons publicity, promoting better habits of sleep.

The work of Public Health Officials and Industrial Welfare Workers, in pointing out the benefits of fresh air and sound, restful sleep, has been consistently supplemented by this Company for a long time. We believe, therefore, that the members of the Medical Profession will be interested in the current advertisements reproduced on this page.

In addition to publicity of this character in the leading newspapers of the United States and Canada, this company is also distributing thousands of instructive and practical booklets upon the all-important subject of *Sleep*. Industrial and Public Welfare Workers are being supplied with the booklet "What the Leading Medical Journals and Health Magazines Say About Separate Beds and Sound Sleep," without cost.

It has been said that cooperation of this character has been of great value to Welfare and Housing Committees as well as to Public Health Officials who conduct "Good Health" departments for their local newspapers.

If you have not yet received a supply of these booklets, we shall be glad to send them to you upon request.

COMBATING CANCER

The recent contribution by Prof. Alexander Fraenkel, secretary of the Austrian Society for Combating Cancer,[1] is commented on in the December 20 issue of *The Lancet*.

Dr. Fraenkel sets out clearly and in detail the pathological facts of human and animal cancer and the results of experimental study of the disease. Due prominence is given to the part played by chronic irritation and the great variety of forms which this factor may take, ranging from chemical irritants to gross Metazoan parasites, such as Bilharzia and the Spiroptera found by the Danish investigator, Fibiger, associated with cancer of the stomach in rats. Fraenkel regards this variety in origin as practically excluding a parasitic etiology of cancer, and he goes on to remark acutely that the same variety in the predisposing factors renders any attempt at a specific cancer prophylaxis nugatory, apart from a general improvement in the prevention of all diseases.

The rare cases of spontaneous cure of cancer, and the more numerous instances of success after incomplete operations, are regarded as of the most happy augury for success in the ultimate triumph of a rational therapy. Early and complete removal is emphasized as still the most successful method of treatment, full recognition being given at the same time to the brilliant results of radiotherapy in suitable cases. Fraenkel then goes on to an account of the chemo-therapeutic experiments of von Wassermann and others, emphasizing the necessity of improved methods of diagnosis early in the disease and of research in this direction.

The article concludes with a severe indictment of the extravagant claims of Adamkiewicz to have produced a practically infallible cure with his cancroin, the soluble toxin of a supposed protozoan parasite of cancer. The danger to the credulous public from such irresponsible claims is not less in other countries than in Austria and, shorn of its verbose and florid style, an article conceived on similar lines and circulated broadcast might do something to put down the raising false hopes by interested people, and to encourage the efforts of those who, without hope of material reward, are seeking the solution of one of the most fascinating as well as one of the most serious problems in medicine.

NATIONAL SAFETY COUNCIL SECTION

MODERN MEDICINE is pleased to announce the consummation of an arrangement with the National Safety Council whereby that organization will conduct a special safety section for MODERN MEDICINE, beginning with the May issue.

Through this arrangement MODERN MEDICINE will be enabled to publish in each issue during the year 1920 a special article on some phase of safety or its allied subjects of particular interest to industrial physicians and nurses. This department will in a large measure make available to the readers of MODERN MEDICINE the valuable service of the National Safety Council—the Nation's clearing house for information on statistics, methods, and experiences in accident prevention, sanitation, and allied subjects. Inasmuch as the National Safety Council is a non-commercial, cooperative association of some four thousand of the country's largest industrial concerns, governmental agencies, and technical schools, its membership includes the great bulk of the safety engineering knowledge and talent of the United States.

1. Ueber die Heilbarkeit der Krebskrankheit, Wien. klin. Wehnsehr, November 13, 1919.

A Nation of Good Workers Is A Nation of Good Sleepers

Public welfare and industrial progress demand that men and women sleep long and deep to build up the vitality wasted by our present day intensive methods of living.

The greater utilization of food for tissue reconstruction is effected mostly during sleep. The deeper the sleep, the more effectively all the processes of bodily repair are carried out.

Hence, the vital bearing which the quality of one's sleep has upon the quality of one's waking activities, is at once apparent.

Mental and bodily vigor are undoubtedly enhanced by the use of a first class mattress.

In the Sealy Mattress every requirement of hygienic design, sanitary construction and physiologically correct service has been met. Only antiseptically cleaned long fibre cotton is used and the special air-weave process makes it a complete unit *without tufting.* This mattress invites deep, restful sleep because of its resiliency, and because of the unbroken, smooth surface which molds itself to support every part of the body.

Electrically Lighted Surgical Instruments

The Sign of Service

E. S. I. Co.

Ours is a name of accomplishment in the cause of diagnosis. In the beginning an electrically lighted surgical instrument is made to embody the ideas of a distinguished physician or surgeon. Each accomplishment by the light of this instrument is a tribute to his skill and its efficiency, opening the way to greater gains for diagnosis and to suggestions for betterments in instrument construction.

Building upon the ideas and from the suggestions of these physicians and surgeons, admittedly great in the respective branches of their exacting profession, is the story of "E. S. I. Co.," from the origination of electrically lighted surgical instruments up to the indispensable service they render today.

Origination begets imitation. Be sure of our name.

CLEVELAND, OHIO

MILITARY ASSOCIATION MEETING

The Twenty-eighth annual meeting of The Association of Military Surgeons of the United States will be held at New Orleans, La., April 22nd to 24th, with headquarters at the Hotel Grunewald.

Three sessions daily will be held and at these addresses will be made on pertinent topics not confined absolutely to the field of military surgery. This meeting occurs immediately prior to that of the American Medical Association whose meeting begins on April 26 and it is hoped that many of those who expect to attend the latter meeting may arrange their plans so as to take in this meeting.

AMERICAN SCHOOL HYGIENE ASSOCIATION

A very important part of the program presented by the National Educational Association at their meeting in Cleveland, O., February 23 to 28, 1920, was the Section on School Hygiene.

"School Health Education in the United States" was the contribution by P. P. Claxton, United States Commissioner of Education, and succeeding papers emphasized the special problems of different communities, rural and urban, and health programs in colleges.

The address of Hiram Byrd on the "Democratization of Hygiene" discussed the needs and the means of stimulating health practices. Special problems of health administration were handled by representative men in their several fields. The notable achievements of the Cleveland, Ohio., schools in sight saving methods for the partially blind were reported by R. B. Irwin, of the Board of Education, Cleveland.

A symposium on the relation of health authorities to school health service was offered, and Frankwood E. Williams of the National Committee for Mental Hygiene, New York City, emphasized the relation of mental hygiene to school health education.

The tendency indicated to direct public interest along the lines of a consistent and scientifically planned program of health education constitutes the best hope of the times.

BRITISH CARE AND TRAINING OF THE BLIND

A bill has been introduced in the British Parliament concerning the care and training of blind persons. It provides that it shall be the duty of every local authority to make sufficient and suitable provision for the technical training, employment, and maintenance of every blind person over sixteen years of age within its jurisdiction.

The local authority is further required to establish and maintain technical schools for the blind, unless arrangements can be made with existing institutions for the provision of such training, in which event the authority shall have power to contribute to the enlargement and maintenance of these places. Technical training is limited to five years, and to persons under fifty years of age. No expense shall be incurred, however, without the approval of the Board of Education.

Further provisions of the bill are that (1) workshops shall be established where arrangements can not be made by the local authority with existing institutions to provide employment, but blind workers may work elsewhere should it be to their benefit; (2) the local authority shall make a grant of £1 (roughly $5) a week for the purpose of increasing the earnings of each blind worker; and (3) such assistance shall not debar the blind person from exercising any franchise or subjeet him to any disability.

HAY-FEVER
Can be Prevented

Industrial physicians and health officials will be especially interested this year in Pollen Antigen because through its use absenteeism and lowered production due to Hay-Fever can be prevented.

CLINICAL results covering more than 12,000 cases, attest the value of **Pollen Antigen.**[1] During the past five years, from 1915 to 1919 inclusive, **Pollen Antigen** has afforded relief from hay-fever by conferring an average protection of 82.7%.

THE treatment with **Pollen Antigen** should be started six weeks before the date of the usual onset of hay-fever. Even in those not protected, the symptoms are usually rendered mild and the attack cut short.

POLLEN Antigen is now universally used for hay-fever because:

1. Contains all the antigenic properties of pollen grains.
2. Will not deteriorate.
3. Standardized by complement fixation.
4. May be used without preliminary diagnostic tests.
5. Gives uniformily consistent results each year.

REQUESTS for further information are invited.

Food Cells All Exploded

Puffed wheat is whole wheat, better-cooked than wheat ever was before.

The process was invented by Prof. A. P. Anderson, formerly of Columbia University. And it is this:

Whole grains are sealed in huge guns, then revolved for an hour in 550 degrees of heat. The trifle of moisture inside each food cell is thus changed to steam.

Then the guns are shot and the steam explodes. Over 100 million explosions occur in each kernel—one for every food cell.

The grains are puffed to bubbles, eight times normal size. They become flavory tidbits, thin and crisp and flimsy. And every granule is fitted to easily digest.

So with all the Puffed Grains. All are steam-exploded. All are delightful foods. You find many conditions where such foods are ideal for your purpose.

INFANT MORTALITY A SOCIAL PROBLEM

From a recent study of the poor in London's East Side, conducted by the National Birth Rate Commission of England, Dr. C. W. Saleeby, chairman of the Commission, declares that infant mortality is not really a medical problem, but is a social problem of motherhood and a question of racial morals.

Jewish mothers are best, he says, and the Irish mother is second, with the English mother third in rank. Breast feeding is almost universal among Jewish mothers, and among them there is a minimum of morality diseases.

Figures are quoted to the effect that despite bad housing, bad sanitation, and the practical absence of child welfare efforts, infant mortality in western Ireland is only about thirty-five per thousand, as compared with 135 per thousand in Bradford, Eng., which has the best equipment for infant welfare work in the world.

DO MOVIES HURT THE EYES?

"The fact that millions of people go to motion picture shows throughout the United States daily without experiencing any discomfort to their eyes, or that such eye trouble that is found is not traceable to 'over indulgence' in the movies, would seem to indicate that motion pictures are not injurious to the vision," says the United States Public Health Service.

"It is true, of course, that some people do experience a certain amount of eye strain at a motion picture, but in these cases the trouble appears to be due to an ocular defect rather than to the motion picture. Such persons should therefore have the eyes examined by a competent eye specialist, for it is quite certain that the same person would find even more discomfort in the same period of concentrated reading. Eye discomfort in the movies should be regarded as a danger signal and should lead the sufferer to the doctor's office for an examination."

BRINGING HEALTH TO THE PEOPLE

The necessity for efficient organization to bring health to the people, and some of the defects of health programs in the United States form the subject of an address by Lee K. Frankel, Ph.D., president of the American Public Health Association, as reported in the February issue of the *Ohio State Medical Journal*. He regards the work of the public health officers in the United States as incessant and as but slightly appreciated notwithstanding the fact that their activities during the past thirty years have brought about marked reduction in mortality and morbidity. Their salaries are inadequate and the health appropriation far below what it should be. "We must find the means through legislative enactment and through public opinion to see to it that we obtain appropriation for public health work that will place on our statute books laws which will give us full-time health officers. . . . The day is coming when we shall have tried to live up to that old biblical promise that a man shall live three score years and ten."

NO MORE PARTIAL DISABILITY

After March 1, 1920, no insurance policy will be written which contains a partial disability clause for sickness, according to announcement made by the *National Underwriter*. Partial disability has long been a bugbear of insurance companies. Decisions in such claims are always open to question, and that disability clauses probably should have been dropped long ago is the opinion of most insurance men.

Quick Relief

from the painful symptoms of Gonorrhoea will be appreciated by your patients. Gonosan promptly allays the severe pains, the burning and priapism.

In Urethritis and Cystitis

GONOSAN

has proven highly effective in limiting the course and extent of the inflammation. Its comparative freedom from irritating effects upon stomach and kidneys emphasizes its value as the best coadjutor of local treatment. Literature and samples from

FOR DIET CONTROL IN INFANT FEEDING

The choice of these dependable products affords the physician convenient means of selecting food mixtures suited to the individual requirements of individual cases.

MEAD'S DEXTRI-MALTOSE NO. 1

(With Sodium Chloride 2%)

For general use in infant feeding. Especially indicated in infants recovering from diarrhoea, infants with feeble powers of digestion who have tendencies to diarrhoea. Valuable as an addition to Protein Milk.

MEAD'S DRY MALT SOUP STOCK

For difficult feeding cases. Indicated in marasmus, weight disturbance (failure to gain), infants afflicted with recurrent diarrhoea from intestinal indigestion, and those cases occasionally met which do not do well on milk, water and sugar mixtures.

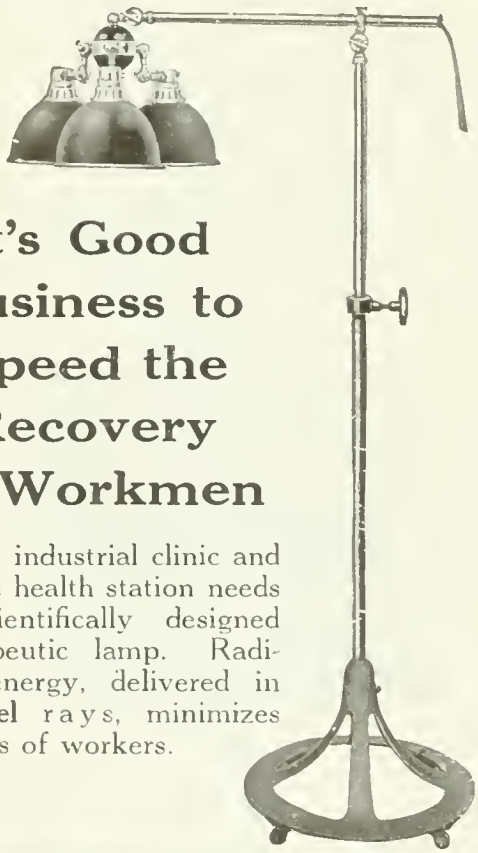
MEAD'S DEXTRI-MALTOSE NO. 3

(With Potassium Carbonate 2%)

For use in constipation, when boiled feedings are used, or where the addition of potassium to the infant's diet is indicated.

Full information regarding these products furnished on request.

MEAD JOHNSON & CO. **Evansville, Ind.**



It's Good Business to Speed the Recovery of Workmen

Every industrial clinic and public health station needs a scientifically designed therapeutic lamp. Radiant energy, delivered in **parallel** rays, minimizes layoffs of workers.

Thermolite
LIGHT AND HEAT INFUSER

Delivers Radiant Light and Heat in PARALLEL Rays

Extremely effective in the treatment of—

Neuralgia	Gastralgia	Rheumatism
Arthritis	Earache	Lumbago
Dermatitis	Laryngitis	Neuritis
Dismenorrhea	Mumps	Ulcers
Shingles	Bronchitis	Cystitis

and many other conditions.

...nd for ... and free book. Ph to the ad...

ThermoLite is supplied in two forms the **Triplex** for hospital clinics and office use, and **Simplex** (single lamp with or without stand) for home use.

39 Warren St., New York City

FIGHTS DISEASE IN THE HOLY LAND

American standards in the care of the sick and in preventive health work are revolutionizing the ancient and abominable conditions in Palestine. Hospitals and emergency stations equipped with highly trained surgeons are already established, and in Palestine there is in operation a training school for nurses. Henrietta Szold, formerly of Baltimore, but for the past fifteen years of New York, editor of many works of Jewish progress, and secretary of the Jewish Publication Society from 1893 to 1916, has recently been appointed by the American Zionists' Organization to give expert supervision to the medical unit.

Once before Miss Szold investigated health conditions in Jerusalem, when in 1909 she observed the terrible ravages of cholera and spotted typhus. At that time she conceived the idea of district nursing, and on her return she organized "Hadessah," the woman's branch of the Zionist movement. It is conceded that Miss Szold brings to her task all the requisite attributes for its successful prosecution.

NON-SPECIFIC IMMUNITY

The seasoned soldier is more resistant even to newly imported infections than the recent recruit. Especially are those used to crowd life able to resist respiratory infections, according to Dr. Victor C. Vaughan, in the January issue of *The Military Surgeon*. From the Army experience of 1917-18, Dr. Vaughan deduces:

(1) That when armies are recruited and men from all fields of life are crowded together, those from areas sparsely settled and who are unaccustomed to crowd life will prove most susceptible to infections.

(2) That the man who has been long accustomed to crowd life and who has consequently frequently inhaled particulate protiens (bacteria), acquires a non-specific immunity, which helps him in withstanding infection.

(3) That the seasoned soldier bears even newly imported infections better than his comrade who has recently joined the ranks.

Such non-specific immunity does not operate to prevent infection from a newly imported virus, but it mitigates the effects in some instances so markedly that no symptoms are recognizable, while in others effects are shown only in the lower death rates among those possessing it. The specific immunity which this non-specific immunity has enabled the individual to attain may protect against from eight to twelve times the minimum lethal dose.

ADVANTAGES OF URBAN CHILD

That the city child has five times the chance of the rural child to reach maturity is the opinion expressed by Dr. Thomas D. Wood, Columbia University, New York, as expressed before a conference of teachers in New Jersey recently. His opinion is based upon a recent survey of 500,000 children, which proved that country children lead city children in defects of the teeth, defective tonsils, adenoids, malnutrition, and breathing defects.

Ignorance, prejudice, and lack of health supervision were the reasons assigned by Dr. Wood for the poor health in the country.

MISS HAY RECEIVES APPOINTMENT

Announcement is made of the appointment of Miss Helen Scott Hay, of Chicago, as chief nurse to the American Red Cross Commission in Europe. Miss Hay was formerly superintendent of the Illinois Training School for Nurses, and chief nurse of the Red Cross Commission to the Balkans.

The nutrient value of VIROL illustrated in a series of cases, particulars of which have been supplied by medical men.

CASE No. 5

Virol is a valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.
In glass jars:
50c, $1.00 and $2.00.

This wasted little one had been fed nine months at the breast and three months on condensed milk. Wasting continued.

The usual remedies having failed he was put first on a diet of VIROL and barley water, then milk was added. His weight uniformly increased at the rate of six ounces a week. Here he is a fine, bright, healthy child weighing 30 lbs. Case reported in "Medical Times", London, England.

WASTING—Virol is unequalled as a repairer of tissue waste, and is therefore of especial value in all debilitating conditions.

Virol contains the proper proportion of fat so necessary in a perfect diet for invalids and infants. It is assimilated with ease by the weakest stomach.

Virol is widely prescribed as an addition to the food of growing children and in all wasting conditions of children and adults.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

Virol

Used in more than 2000 hospitals, sanatoria, and infant clinics in Great Britain

THE ELLIS HEALTH LAW IN GEORGIA

That inefficiency in health work is largely due to the lack of proper machinery for its administration is again emphasized by the progress in Georgia noted in the January reports of progress under the Ellis Health Law. The advantage of efficient county organization under the operation of the law is exemplified in the report of Dr. B. D. Blackwelder, health commissioner of Troup County During the month he delivered twenty-six lectures, an average of almost one per day; sent out 806 letters, and distributed 1,797 pieces of literature.

He examined, during the month, 760 white school children. Of these 314 had tonsil defects; 185 bad teeth, and 70 breathing defects. As a result of his examination, 62 children had their tonsils removed, 94 bad teeth fixed, 29 eyes treated and 31 breathing defects corrected. There were 216 children in the county who had serious physical defects corrected when the same were called to the attention of their parents.

Dr. Blackwelder also had installed 52 sanitary latrines and 700 home-water supplies, which had been pronounced bad, were made safe. Six new counties are about to qualify under the Ellis law.

A SURVEY OF NEW YORK FACTORIES

The Department of Health of New York announces that its Division of Industrial Hygiene will make a sanitary survey of factories, mercantile establishments, and office buildings for the purpose of ascertaining any conditions which might impair the health of workers. Where a large group of employees is concerned, special clinics will be established for the purpose of making physical examinations. The material collected by the surveys will be the subject of a special report.

MENTALITY TESTS A SAFETY MEASURE

With the announced purpose of putting an end to the operation of street cars and trains in Berkeley, Cal., by "feeble-minded, insane, epileptic, psychopaths, neuropaths, drug fiends, and other incompetent persons," the city council of Berkeley has passed an ordinance providing mental tests for all operators. The mental requirements are rigid and are to be given by members of the psychopathic clinic of the Berkeley police department, under Commissioner of Health and Safety Charles E. Heywood, Chief of Police Vollmer, and a medical psychologist to be selected by the others.

A CHILDREN'S BUREAU IN CALIFORNIA

The establishment of a Children's Bureau in California under the direction of Dr. Ethel Watters is a signal step in advance in the public health program of the state. The department proposes to establish maternity or pre-natal centers sufficient to provide for all cases not receiving care from private physicians. They will undertake to enforce complete birth registration and to provide health centers for children of pre-school age. The program will also include general educational work in the prevention of communicable disease in hygiene and infant feeding, and a compulsory course in child hygiene in public schools.

TYPHUS MORTALITY CUT

The mortality from typhus fever has been reduced from 47 per cent to 6 per cent by the use of a new serum adopted by Red Cross workers at Ekaterinodar, in the Kuban district of Russia according to reports received. This serum may save Russia from decimation by typhus.

TUBERCULOSIS SCHOOL INCORPORATED

A number of physicians of Colorado Springs filed an affidavit, January 1, for the incorporation of the Colorado School of Tuberculosis, the purposes of which are described as follows: "To furnish without pecuniary profit to its members, opportunity for special advanced study in tuberculosis to physicians and others through the medium of regular courses of instruction and institutions, and laboratories and other agencies devoted to investigation, treatment and cure of the disease."

"A POOR MAN'S DRUG STORE"

The Salvation Army's hospital and dispensary recently opened at Roxbury, Mass., provides, among other features, a "Poor Man's Drug Store," where prescriptions will be filled and medicine and other sick room supplies will be offered at cost, or without charge in necessitous cases. This is one of the very few pharmacies of its kind in the United States. The institution also provides ample ward facilities, dental, surgical, operating and x-ray apparatus. Capt. Edward Rudy Gifford is in charge.

NEW THERMOMETER FOR TAKING SKIN TEMPERATURE

The Carnegie Institute nutrition laboratory experiments at Boston made use of a special thermometer for registering the temperature of the skin. The process is thermoelectric, one metallic junction being placed in a bath of constant temperature while the other is applied to the skin. The current set up is directly proportional to the difference in temperature of the two junctions. It has been found that the surface temperature of different parts of the back and chest vary as much as 20 degrees, and it is considered that these indications will prove of value in testing the physical condition.

HEALTH WORK IN JERUSALEM

The activities of the Jewish Health Bureau, established by Nathan Straus in Jerusalem, were continued during the period between September, 1914, and December, 1918, under a variety of difficulties. Some of the members of the organization were compelled to become Turkish citizens in order to carry on their work. The bacteriological department was of the greatest service during the terrible epidemic of cholera, dysentery, malaria, and scarlet fever. The work of the department was not confined to Jerusalem, but included all of the towns of Palestine and all the colonies within its scope of activity. Inoculations against cholera and instructions as to their use were sent everywhere. The bacteriological department carried out 27,290 examinations during the period reported on. It provided 1,491,962 cc. of typhus lymph. It administered 30,750 preventive injections against cholera. The hygienic and malaria department examined the blood of 38,380 persons and provided 154,115 kilograms of quinin. The department of eye diseases discharged 441,874 visits to its clinics. In the department's hospital, 436 severe operations were carried out. Patients passed a total of 6,042 days in the hospital. The Bureau conducted two clinics for eye diseases and found it possible to open a museum of hygiene which now contains collections of models illustrating the conditions of life of the native population from a hygienic point of view, an herbarium of medicinal plants native to Palestine, and a collection of photographs illustrating the water cisterns in Jerusalem and the development of the typical diseases of the country.

NOTES AND COMMENT

AMERICAN MEDICAL ASSOCIATION

THE city of New Orleans was taxed to its utmost to provide accommodations for the large crowds of physicians and surgeons who journeyed there to attend the annual convention of the American Medical Association April 27 to 30. Many of the allied associations who regularly hold their meetings with the American Medical Association were also in attendance at the same time in large numbers. The combined interest in scientific discussion and in the health and medical problems of the Southland drew an unexpectedly large crowd to the conventions. There were the usual scientific productions, valuable exhibits of medical progress, and keen interest in practical problems. To the readers of MODERN MEDICINE the three sessions of the Section of Preventive Medicine and Public Health were of special interest.

The Association discussed ardently some practical questions of policy. Among others, the subject of Workmen's Health Insurance received perhaps the most earnest attention. The House of Delegates went on record in disapproval of health insurance, but recognized the necessity of analyzing the conditions which through this issue have come into prominence. A resolution directing an investigation of those conditions by the Council on Health and Public Instruction offers the members the possibility of scientific proposals on the medical needs which brought health insurance to the front.

The address of the president, Rear Admiral William C. Braistead, took a firm stand for a national department of health, declaring that a great, rich country should not depend upon enlightened millionaires to perform the obvious duty of looking after the public health. Admiral Braistead declared, also, for a broad program of child hygiene and general preventive measures.

INDUSTRIAL PHYSICIANS MEET

THE annual convention of the American Association of Industrial Physicians and Surgeons held at New Orleans April 26 and 27, 1920, was attended by a small but enthusiastic body of industrial physicians and surgeons from all parts of the country. Those who took the long trip were well repaid by the excellence of the program and the practical nature of the discussions.

The address of the president, Dr. Harry E. Mock, was a very practical vision of the future of industrial medicine. "Wound Infection in Industry" was succinctly treated by Dr. Drury Hinton, of E. I. du Pont de Nemours & Co. Dr. J. A. Watkins, of the Lunkenheimer Company, Cincinnati, reviewed the progress of training for the industrial physician. Dr. Edward Martin, commissioner, Department of Health of Pennsylvania, outlined the very practical plans of the Pennsylvania Department of Health in the treatment of venereal disease. A scientific contribution to the subject of industrial physiology was given by Dr. A. H. Ryan of the Scovil Manufacturing Company, who dealt with the subject of fatigue and efficiency tests.

The subjects which excited the most earnest discussions were those of the round tables on "The Problems of First Aid," "Standardized Surgical Methods in Industry," and "The Problem of Compensation for Sickness." The first brought a re-

view of the actual plans in operation in industries in handling and treating first aid cases. The second brought out the fact that standardized methods are out of the question but that minimum standard may be established on which there would be an agreement. The third gave a résumé of the argument for and against health insurance as proposed in this country. The presence of Dr. Norman Walker of Scotland, who spoke favorably of the English experience, was of special interest.

In addition to the program of the Association the subject of industrial medicine was treated in several contributions to the Section on Preventive Medicine and Public Health of the American Medical Association.

The Association of Industrial Physicians and Surgeons went on record for an enlarged program for the promotion of industrial medicine. An aggressive policy was agreed upon to promote membership and increase the service of the Association to its members. The dues were increased for this purpose, and optimism was expressed on all hands in regard to the work to be done.

Officers were elected as follows: Dr. Otto P. Geier, of the Cincinnati Milling Machine Co., was elected president; Dr. I. R. Crowder, of the Pullman Co., Chicago, Ill., vice-president; Dr. W. Irving Clark, of the Norton Co., Worcester, Mass., second vice-president; and Dr. Francis D. Patterson, Department of Labor and Industry, Pennsylvania, secretary-treasurer.

"HOSPITAL PROGRESS"

MAGAZINES with a mission are always welcome. We extend hearty greetings, therefore, to *Hospital Progress*, the official organ of the Catholic Hospital Association, which begins this month a career of assured usefulness and inspiration.

In modest terms the new magazine states that it "wishes to become the medium through which the best thought and practice in hospital service to the sick will be worked into the lives of those who are consecrated to this service. . . . Consecration to service must be wrought into the lives of all who care for the sick. . . . Hospital Progress wants to help all to realize more and more deeply from month to month that care of the sick is and must become in very deed a consecration of mind and heart and soul."

With the backing of more than five hundred Catholic hospitals which have been striving for many years, aye, centuries, to realize this goal, and the cordial support of all hospital workers, doctors, nurses, and laymen alike, who believe in and strive for service to the sick, there is a place and a large place for the new magazine.

HUBERT WORK M.D.

President-Elect American Medical Association

The election of Dr. Hubert Work, Pueblo, Colo., as president of the American Medical Association brings to that office a man especially fitted by training and experience for the efficient discharge of the important and urgent problems that confront the Association at the present time. Dr. Work was born near Marion, Pa., July 3, 1860. He graduated from Indiana, Pennsylvania, and California state normal schools. He received his degree in medicine from the University of Pennsylvania in 1885. He has served as physician in charge of Wooderaft Hospital. As Colonel in the Medical Reserve Corps he was adviser to the Provost Marshal General. He has been a member of the House of Delegates of the American Medical Association since 1904, in which Body he has held the office of speaker since 1916. Dr. Work's career has been marked by a high order of public service. His equipment and parliamentary experience especially fit him for the post to which he has been called by the profession. Nor have his activities been confined to medical matters. He is one of the few physicians in the country who have achieved political distinction. His candidacy for the United States Senate was defeated by only a small majority, and for several years he has served his state as a member of the Republican National Committee. His war service has been mentioned. Under his official direction the Association cannot fail to be marked by progress and increased cooperation.

THE SOCIAL ASPECT OF THE CARDIAC CASE

IN the treatment of cardiac disease the clinician whose experience ranges from the charity wards of the hospital or dispensary to the well-to-do patient must realize that there are two facts which characterize the situation. It is not often commented upon but it is nevertheless true that the majority of cardiac patients of means rarely have to spend time in a hospital. On the other hand, the free wards of a hospital are always rich in cardiac material and frequently this material consists of patients who have been in before and who surely will come in again. The cause for such an anomalous state of affairs is recognizable as one dealing purely with the economic problem of the individual patient. Even after a cardiac breakdown after-treatment can be summarized in a sentence, "The patient must keep under his tolerance if he is to retain his health and working efficiency." It is naturally easy for a man of means so to regulate his affairs as to cut his work in two, get the requisite rest, and the trips to healthier climates when necessary; but it may be impossible to carry out proper medical treatment of the poorer cardiac patient.

This, in brief, is a statement of the treatment of heart disease today; and this the reason why a discussion of the social aspect of the cardiac case is a matter of interest by medical workers. Thompson[1] studied the problem purely from the social aspect. She states that with the increasing interest in the anti-tuberculosis campaign there has been a gradual diminution in the proportion of deaths from tuberculosis and a gradual increase in the deaths from heart disease in the United States, in Indiana, and in New York City. Figured on the basis of cost, Miss Thompson reckons that more than five million dollars were lost from death due to heart disease in twelve months time.

The causes of heart disease are discussed by her under the summary: "Cardiac disease may almost be said to be a by-product of some other disease in every instance. Protect the patient from the primary disease and the heart will not be injured further. Subsequent management can control the strain placed upon the damaged heart so as to prevent the possible cardiac failure."

Under the heading of medical and social treatment, the statement is made that since the advent of preventive medicine treatment is divided into three main groups: (1) treatment of cardiac children; (2) adults; (3) convalescents. The work of the Massachusetts General Hospital has shown the possibility of improvement in the treatment of children, while Bellevue's Sharon experiment has proved the advisability of continuing hospital treatment of adults in a convalescent home where some suitable occupational training is instituted.

Her statistics on patients who are still living are interesting. Of a total of 70 cardiac patients seen in the city clinic only 17 were born in the city; 19 came from the small town; 19 from the country; and the place of birth of 15 was unknown. The occupations of the men were almost entirely those belonging to the class of hard labor. The occupations of the women were, strange to say, in the home. It seems wise to emphasize an often neglected fact, namely, that housekeeping, especially under the strain of modern domestic life, is far from being the sinecure so many men seem to consider it. In fact, from the statistics of Miss Thompson the housewife belongs to the class of hard laborers.

The conclusion of the social worker can be read with considerable benefit by the physician. She says, for instance, "doctors should not be satisfied to treat an infectious disease and pay little or no attention to the endangered heart." (Doctors are now seeing cases of myocardial degenerations which unquestionably followed the influenza epidemic of 1918 and 1919, although at the time of the epidemic it was constantly stated that the heart escaped.) "Mothers with little children should be warned against taking a weakly child where it may catch an infectious disease. Hospital doctors should be careful not to dismiss a cardiac case before sufficient compensation is established or before the social worker has investigated the conditions to which the patient is to return. After leaving the hospital the greatest difficulty in treating such patients now occurs." Beyond general suggestions Miss Thompson's study does not help much here. Purely from the standpoint of social economics it is a community duty to see that the cardiac patient, after leaving the hospital, is not forced into a situation from which in a short time he must again enter the hospital and which will ultimately result in total economic disability and finally death. Beginnings even small must be made in the out-patient departments of hospitals, and in convalescent homes, for it is in these institutions the needs of the patient must be worked out, and only through this service may we look toward a real rehabilitation of this type of patient. The principle is simple enough; the practice, as Miss Thompson says, depends to great extent on the attitude of the community and especially of the legislature. S. S.

1. Thompson, Lela Frances, A.M.: Indiana University Studies, Study No. 42, The Social Aspect of the Cardiac Case. A Study Based Upon One Hundred Fifty-four Cardiac Cases Referred to the Social Service Department of Indiana University.

THE RECONSTRUCTION OF THE SICK CHILD*

By A. LEVINSON, Chicago

In the healing arts, disease is of the same interest to the physician that a mental crisis is to the psychologist—a phenomenon to be studied, a situation to be met. But the chief concern centers on the general reaction of the organism and its ability to resume a normal course.

The entire mechanism is to some degree permanently damaged by every onslaught of disease, and the physician needs to stand by long after the acute attack.

What regeneration cannot accomplish in the way of restoration, the physician must compensate for in a prescribed régime which will shorten the convalescence and reduce the permanent handicap.

OF late a great deal of attention is being paid to the prevention of disease in children and to the treatment of sick children. There is one phase of the subject, however, which as yet has not been elaborated upon, and that is the convalescent child, his state of body and mind, and his physical and mental needs. The subject seems to be of such vital importance as to justify a short discussion of it in this journal, for an intelligent control during convalescence may depend the degree of restoration.

At the outset, it is wise to understand what we mean by convalescence, and how long a period convalescence embraces. Convalescence is the period of recuperation; it is the period elapsing between the height of the disease that attacked the individual and the time of his return to his normal state of health. The length of this period is necessarily arbitrary, depending on the nature of the malady, the amount of damage it has produced, and the degree of resistance the patient has left from the disease. Convalescence may take one week, one year, or it may require the rest of the individual's lifetime. Some children recover from measles within a week or two; others do not recover for the rest of their lives.

In order to understand the finer points of convalescence, one must get an insight to the pathology, or to the so-called pathological physiology of both disease and convalescence. There is no disease attacking the human organism which does not eventually leave its imprint on every organ of the body. If the disease is at all systemic, expressing itself in an elevation of temperature, acceleration of pulse, and an increase in the rate of respiration, the parenchymatous organs of the body suffer sooner or later. In some diseases the heart muscle suffers most, such as is the case in diphtheria; in other diseases the kidneys suffer most, such as occurs in some cases of scarlet fever. There is, however, no disease of any account that leaves any of the more important organs of the body undamaged. If no actual inflammation or degeneration of the organs occurs, there is at least a lowered resistance of the more important organs of the body, and therefore also a change in the physiology of the organs. In other words, every organ loses a certain degree of its power to perform the normal amount of work consistent with the natural state of the body. This is true in all ages, but is especially true in children, in whom the organism is in a state of constant change and needs double or triple the amount of energy required of the organs of the older individual.

Synchronous Changes in Organs

We can no longer separate diseases into stages, assigning each stage a certain change in the various organs of the body, as was the custom among the older pathologists and clinicians. We can not even, properly speaking, limit the pathology of a given disease to one organ. While it is true that a single organ may bear the brunt of change in certain diseases, every other organ necessarily partakes of some changes, so that, while the intestines bear the brunt of the disease in typhoid fever, every other organ in the body feels the effect of the disease; and while the meninges is mainly affected in meningitis, every other part of the body suffers concurrently in that disease.

With this broader understanding of the pathology of disease, convalescence assumes greater importance from the standpoint of prophylaxis and treatment. Once it is appreciated that every disease attacks every organ in the patient's body, we can not make light of the period of restoration or reparation. It is necessary for every organ of the body to regenerate, to replace the damage done, and to gather new vitality. Some of the damage done can never be replaced. A broken heart can never be mended; an ulcerated lung can never be patched up. However, if the lesion has not been extensive, it is possible for regenera-

*The first of a series of articles dealing with medicosociologic problems in the field of pediatrics to be prepared by Dr. Levinson for the pages of Modern Medicine.

tion to take place if too much strain is not put on this very organ, and here arises the necessity for a proper understanding of convalescence. Unless the physician in charge of the convalescent patient—and it is urged that every convalescing patient must be in charge of a physician—has the proper understanding of convalescence, of its pathology, of its physiology, of its inherent dangers, and of its potency for the good of the patient, the convalescent period may not only fail of benefit, but may constitute a progressive stage of the disease.

One cannot, of course, lay down any hard and fast rules as to treatment during convalescence. The treatment must necessarily vary with the disease and with the patient. Still there are some generalities that can be outlined. This we have attempted to do.

Role of Rest in Prevention

Just as it is necessary to preserve the child's energy during disease, so is its conservation essential during convalescence. In fact, it is more important to conserve energy during convalescence, for during the actual illness a child is too sick to overexert himself, while during convalescence, when strength is just beginning to return, the child is likely to overexert himself and thus cause a dilatation of the heart.

Experience has shown that the best way to prevent a carditis during disease or convalescence is to give the heart rest. Rest in bed is necessarily the best way of taking off the burden from the patient's heart. When one considers the enormous number of children who are laid up in their homes and in hospitals with cardiac trouble, the conclusion must follow that possibly we are too lax in the after-treatment of children's disease, that possibly we do not keep our patients long enough in bed after the subsidence of an acute infectious process. It is hard to keep well children in bed. No sooner does a child's temperature drop, but he wants to be out of bed and to return to normal activity. However, the danger of overexertion on the part of the heart makes it imperative to give the heart an extended rest, and reeducate the child slowly in regard to resumption of his normal activities.

The Need of Sunshine and Air

"I suppose I cannot take the child out for another two or three weeks," is the usual intonation of the mother during the child's convalescence. This same mother used to take her baby out for fresh air during the severest storms, when cattle breeders would not allow their stock to be outside; yet, after the child had pneumonia, she would keep it in, in spite of the lack of sunshine in the house and the abundance of it outside.

I believe it is well worth while to emphasize that, while a convalescent child needs rest, he also needs sunshine and air, even more so than a healthy child. It is, therefore, imperative to give the child a chance to be out on the porch in his wheel chair when the weather permits, and gradually to get him used even to cold air.

Food Requirements

Contact with physicians has taught me that two extremes are allowed in feeding convalescent children. One group of men overfeeds the children and the other underfeeds them. The first group insists that the convalescent child needs strength, which it must get through an abundance of food. The other group insists that the convalescent child can not digest even ordinary food.

The truth seems to be between the extremes. A convalescent child needs proportionately more food than does a healthy child; but his digestive power is not so good. While I usually feed convalescent children more often than healthy children, I believe the decision can in most cases be left to the child himself. If he insists on eating, it is a sign that he can stand it. Of course, the food should be as simple as possible. On the other hand, if a child refuses food there is something wrong with his digestive apparatus, and this child should not be overfed, although he should not be starved, but should be given enough food to sustain him.

Restore by Constructive Play

In another article[1] we have discussed at length the psychological changes occurring during a child's illness. Here it becomes important to understand the child's mental attitude during convalescence, and all efforts should be exerted to restore him to a normal psychological state. This can be done by studying the child's peculiarities, by furnishing him sufficient toys, and by teaching him to do something. Constructive play is important throughout childhood, but is doubly important during convalescence. The child begins to feel that he is doing something, that he is constructing, that he is of value. Of course, the work must be regulated so as not to overexert the child. Well planned, easy, constructive play is far from harmful and may be of the greatest importance to the convalescent child. Directed play provides a normal outlet for the nervous impulses of the convalescent child. The utmost skill may be required to guide him out of the pathologic attitude and to prevent later neuroses.

ST. FRANCIS' COUNTRY HOUSE FOR CONVALESCENTS AT DARBY, PA.

ST. FRANCIS' Country House for Convalescents undertakes the restoration of patients with reduced nervous control. It provides rest and strives to inculcate the habits which are essential if a complete cure is to be achieved. It was founded for the free care of convalescent women. The need of such a place had been long felt, and its establishment often agitated. During the winter of 1912-1913 interest was revived in the project when several Catholic ladies asked the Archbishop's blessing on the work. After some discussion, a meeting was called at the residence of the Chaplain of Blockley (City Hospital) in May, 1913. Those who answered the call represented the Children of Mary of the Sacred Heart Convent, who have maintained a visiting committee at Blockley for the past forty years, the Almshouse Committee of the St. Vincent de Paul's Conference, and several women prominent in the St. Vincent's Aid, Ladies of Charity, and the Christian Mothers. It was agreed that sufficient resources were at hand to begin the work at once. With the Archbishop's approval, a most suitable and convenient property was secured, consisting of a colonial mansion, part of which was built in 1785, on the brow of a hill in an estate of twelve acres, skirted by Darby Creek. The land is part of a grant of 350 acres made to John Blunston, one of the Quaker settlers of Darby, by William Penn. It is of interest to note that it was also owned at one time by John Bartram, the botanist.

The place is well adapted to its present use. There the patients may enjoy the wholesome air and restful quiet of the country, while to reach it they are not put to the expense and trouble of a long journey. Its proximity to the Darby car line makes it easy of access from all sections of the city. One of the drawbacks of most convalescent homes is their too great distance from the people whom they are intended to benefit. On condition of an option to buy within a year, rental of this property was fixed at $50 a month. The first year's rent was very generously donated by Mr. M. P. Quinn. Through the untiring efforts of the Women's Auxiliary the sum of $2,400 was collected for repairs and general furnishings. The Men's Committee, agreeing to meet current expenses, collected about $2,700.

St. Francis' House was opened in June, 1913, when it possessed but fifteen beds. Mrs. Charles P. Mullin, who had done splendid work at Blockley, volunteered to serve as manager. The first patient was received June 30. The success of the undertaking was so rapid that now, at the end of only five years, there is accommodation for fifty persons. It is seldom that all the beds are not taken; indeed, usually there is a long waiting list. Beds have often to be improvised. Every effort is made to avoid the atmosphere of an institution and to have the surroundings as homelike as possible. There is the minimum amount of red tape, always so repugnant, for obtaining admittance. The House is open to all women, of what-

ever nationality or creed, who are over the age of twelve years and in need of convalescent care.

Admissions are made through the Admissions Committee, which meets every Thursday. Any emergency case is acted upon by the resident manager in the interval between meetings. No charge is asked for or accepted, for the House is intended solely for those unable to pay for their care elsewhere. The religion of those entering is never inquired into. They are permitted to go to any church they may choose on Sunday and, if unable to walk, they are driven in the House automobile. There are few rules, and these only such regulations as are strictly necessary. Visitors are permitted every day. This broad ruling has been found very beneficial, as patients isolated from their friends are very subject to loneliness and depression, which seriously retards their recovery. Those physically fit are occasionally asked to help with some of the light work around the House, but after the dormitories are put in order the guests are practically free for the rest of the day. In the summer they may roam around the spacious grounds or rest peacefully under the cool shade of the trees. This is no small boon to those who are accustomed only to the hot, cramped conditions of our city's poorer sections. In the winter the glass-enclosed porch supplies a very comfortable sun parlor. This porch is furnished with a plentiful supply of couches and easy chairs. Down the center are tables for reading and writing,—the gift of the Women's Auxiliary. There are many books and magazines at hand. There is also a phonograph, for which the Juniors see that there are always fresh records. Nothing is lacking that is necessary for comfort and recreation.

Directed Occupation Aids

An occupational teacher instructs the guests in interesting work that distracts their thoughts from themselves. Mrs. Mullin, the superintendent, gives her services gratuitously. She takes a keen personal interest in the work, so that the patients are sure of kind, motherly attention at her hands. There are few paid workers at Darby, so that only about one-fifth of the running expense is for administration, which is a remarkable tribute to the generous charity of the administrators of St. Francis'. In consequence of this and the fact that the House has its own supply of vegetables, milk, and eggs, and the cost of each patient per month until recently has been only about $12 to $14. Now, however, owing to the increased price of everything, the average cost is a little more than $15.

This beauty spot, the picturesque Grotto of Our Lady, is formed by the rocks on the slope of ground back of the house. (Photo by Perry A. Wiley, Darby, Pa.)

Patients are permitted to remain until their strength is recovered. The average length of stay is about four weeks. There is a visiting physician with final decision on the discharge of patients.

A visiting committee follows up certain needy

patients after their discharge, and by a few helpful suggestions endeavors to make permanent the benefit derived by the patients' sojourn at Darby. In many cases this involves finding suitable employment for them.

The interest shown by patients in one another, even after they have left the House, has led to the adoption of yearly reunions on Labor Day. The great number who return on these days is significant of their gratitude and of their appreciation of the great good of St. Francis'.

For its support St. Francis' depends solely on charitable contributions. Through the splendid efforts of the Men's Committee, nearly $25,000 was raised in fifteen days to purchase the property. The members of the Women's Auxiliary and the Junior Aid are untiring in their labor for this institution. In addition to much other work, these ladies hold annually, on the grounds of the House, an alphabetical fair and market day. The Juniors have been very successful in the annual production of a play by which they have obtained large sums for the convalescents. In all, St. Francis' has received from various sources more than $150,000 in six years. Besides gifts of money, there are many individual contributions of food, clothing, and furnishings.

Many repairs and changes have had to be made in the House. New bathrooms and a new staircase were necessary. The rooms and halls had to be repaired and repainted, and a new heating system installed. A new road leading up to the House required to be made. These are only some of the more extensive improvements. For a time a mortgage of $10,000 was placed on the property, but was afterwards lifted by the late Michael Murphy, so that now the place is free of all debt. An additional $10,000 was bequeathed by Mr. Murphy to St. Francis'.

The success of St. Francis' since its inception has been phenomenal and is indicative of how greatly such an institution was needed. During its short career it has received about three thousand cases. These figures represent only the individuals who owe renewed life and vigor to the convalescent home. They give no idea of the many families that received a new start through the return to good health of an ailing mother or a bread-winning sister.

Front and side view of the original house of St. Francis' Country House for Convalescents. The setting of trees and the twelve acre grounds are in keeping with the dignity and placidity of the building.

Medical Service Provided

There are many happy features that characterize St. Francis' and seem to account for much of its popularity, chief among which are its nearness to the city, its strictly non-sectarian character, the ease with which admission is obtained, and its decidedly homelike atmosphere—the result of the absence of institutional rules. While St. Francis' has always a waiting list, investigation has shown other convalescent homes to be rarely filled to

Patients knitting for the soldiers.

Camping out on St. Francis' grounds.

their capacity. Social workers in Philadelphia say that the patients love to go to St. Francis', and it seems that the workers themselves are no less desirous to have them entered there

During 1917-1918 there were received 892 applications for admission to St. Francis' Convalescent House; 732 were approved and admitted; 103 were refused for various reasons, principally because of tuberculosis and epilepsy in the applicants; and 57 failed to come after being sent for. The majority of these applications were received from the hospitals, social service, and various other organizations in and about the city. By far the greatest number was received from the hospitals for patients recovering from operations or some serious malady, who were in need of the rest, food, air, and change of environment to be found at St. Francis'.

Poultry yard where the feathered flock contribute to the support of St. Francis' Country House convalescents.

A certain number of children accompany their mothers. During the year there were seventy-two mothers with babies under one year, ten mothers with twins under one year, and one mother with tripets under one year.

However, arrangements have been made with neighboring institutions for the care of infants and children during the period of convalescence of the mother, thus assuring the mother a quicker return to health. An excellent addition would be a building where all children could be cared for, which would relieve the mothers and give them the necessary added rest. It would at the same time centralize the care of the infants.

A large number of applications have been received for the admission of tuberculous patients, but the lack of accommodations for the care of this type of patient makes it necessary to refer them to special institutions. St. Francis' does not provide care for the incurably incapacitated, but receives any woman who through non-contagious disease, operation, or overwork is found in need of rest and change.

The 700 cases received in the first two years represented patients from fifty-five institutions,—thirty-two hospitals in Philadelphia, three hospitals out of town, and twenty other organizations, such as the Courts Aid Association and the charity organizations. The diagnosis were classified under 113 headings.

Patients received directly from their own homes numbered 132 in this two-year period. The record of benefits received shows 63 improved, 63 markedly improved or cured, and six not improved. Of the whole number received, 738,—which includes 60 mothers with babies,—364 were discharged as cured, 284 as improved, and 30 unimproved.

Valuable service has been rendered in cases complicated by nervous disorders. Provision is made for patients suffering from melancholia, neurasthenia, depressive mania, and even from dementia praecox. It is well recognized that one of the most important factors in the causation of insanity is strain, mental or physical. Many cases received at the Convalescent Home exem-

plify the curative effects of quiet and change of environment, and the relief of strain under the right régime. A number of these patients with reduced mental control have been restored to health. A few typical cases referred by the Social Service Division of the Philadelphia Department of Public Health and Charities are cited to show the constructive value of this phase of the work.

Jennie, age 45. Admitted to hospital, psychopathic ward, October 7, 1916. Discharged against advice; taken home by husband October 13, 1916. She had attempted suicide and was very depressed and melancholy. Second admission to hospital was on January 22, 1917; discharged February 13, 1917. *Diagnosis:* Nervous exhaustion, with excessive depression and confusion. Sent to St. Francis on day of discharge, leaving there after a stay of six weeks, in excellent condition, with a gain in weight of eighteen pounds. She has been keeping house ever since and doing very well. She had not been able to keep house for two and a half years prior to her stay at St. Francis.

Marie, age 53. Admitted to hospital, psychopathic ward, March 7, 1917. Discharged April 13, 1917. She refused convalescent care. Second admission May 26, 1917. She was in the insane department from June 14 to September 1, 1917. *Diagnosis:* Recurrent melancholia. She was sent to St. Francis on day of parole from hospital, where she remained for one month, gained twelve pounds in weight, and was entirely well when she returned to her home. Has been keeping house for her two brothers ever since. She became active in church and social affairs, which she had not been able to do for eighteen months prior to admission to the hospital.

Mary, age 39, married, mother of three sons. She was admitted to hospital July 6, 1916, discharged August 10, 1916. Had been addicted to drugs, paregoric, using a maximum of two pints per day, which she had been using for eight years. Was separated from husband and children and had been placed in homes. The woman was intelligent, but was an outcast from her family on account of her habit. She was sent to St. Francis August 10, 1916, remaining there for six weeks, at the end of which time she had gained in weight and strength, and had courage and desire to make a new start in life. She was very closely supervised by the Social Service Department, and in six months after her discharge from St. Francis was re-established in her own home, with her husband and children. She has not taken paregoric since, and states, furthermore, that she has never had any desire for it. Has written many letters to worker who sent her to St. Francis, claiming that it was due to the care and influence of the Home that she was able to get back to her old self again.

Cathrine, age 31. Single; stenographer and bookkeeper. Admitted to hospital November 8, 1917. Discharged January 3, 1918. *Diagnosis:* Toxic confusion. She had been sick for eight months and unable to work. She was sent in by her family, who insisted that she be kept in the hospital, and made every effort to have her committed to the insane hospital. Was sent to St. Francis in a fairly good condition, and remained there until April 11, 1918. During six weeks of this time she assisted the matron, and after she left secured a position of responsibility in a large business office where she has been since, earning an excellent salary. She has a deep feeling of gratitude toward the St. Francis Home.

Rosetta, age 50, widow. Sent to hospital from private insane hospital February 9, 1918. She had been there two years and had paid out for her care almost every cent of her income and principal. *Diagnosis:* Depressive mania. She remained in hospital until March 8, 1918, when she was sent to St. Francis Home, where she remained until April 16, 1918, at which time a position was secured for her. Since then she has been in excellent condition until the recent influenza epidemic, to which she fell a victim, and asked to be sent back to St. Francis to regain her strength.

Margaret, age 44, married, mother of two children. She was admitted to hospital, psychopathic ward, May 10, 1918. Discharged to St. Francis Home June 28, 1918. *Diagnosis:* Melancholia. Was in fair condition when she left the hospital. She remained at St. Francis for one month, gained in weight, and was in fine physical condition, with a clear mentality when she returned to her family. She has been keeping house and has remained in an excellent condition.

Margaret, age 34. Mother of three children. She was admitted to the hospital, psychopathic ward, July 14, 1917. *Diagnosis:* Toxic psychosis. Discharged to St. Francis Home August 3, 1917, at which time she weighed only eighty-nine pounds. On leaving St. Francis after a stay of two months, she weighed 123 pounds. Her mental condition having entirely cleared up, she returned to husband and family. She has been keeping house and has continued in excellent condition.
